Supplementary Figure 1. Assessing heparin chain size by SEC and MS. (A) SEC chromatogram and estimated molecular weight of azido-heparin (azHEP, green) clicked to TMR-azide, calculated using a dextran standard curve (Supplementary Figure S3). (B) Intact MS of azido-heparin (Ion trap neg mode ESI) showing deconvoluted peaks at 17,620 or 28,510 Da.

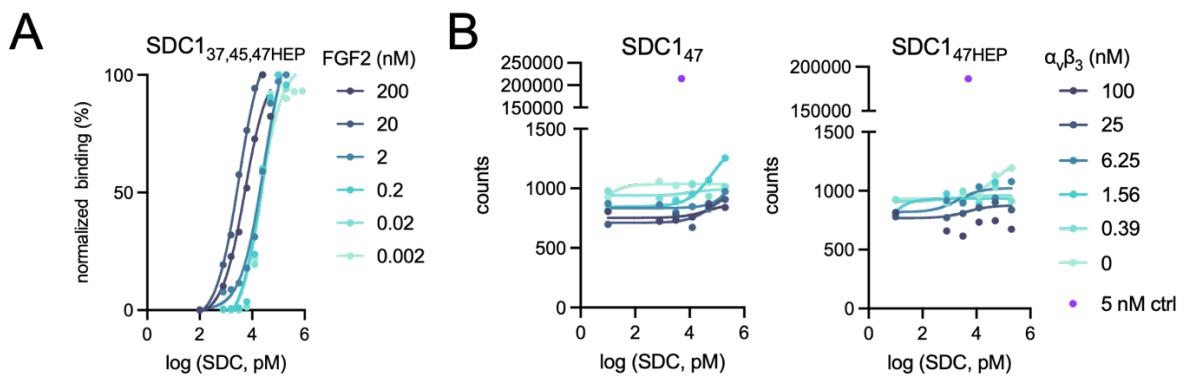

Supplementary Figure 2. Evidence of successful SDC1₃₇GAG conjugation. (A) WAX chromatogram of SDC1₃₇GAG crude reaction products. Highlighted are the fractions collected for SDS-PAGE and Western blot (WB) analysis. These fractions correspond to SDC1₃₇ (grey, $R_t = 9$) and SDC1₃₇GAG (orange, $R_t = 11, 13, 15$). (B) 4-15% gradient SDS-PAGE analysis of collected fractions, transferred to PVDF membrane. Top panel: anti-SDC1 antibody positively stains fractions 9 - 15, detecting higher molecular weight smears (~250kDa) in later fractions. Antibody clone 281-2 has a higher affinity for GAG-conjugated SDC1 relative to non-glycosylated SDC1. Bottom: signal with anti-HS is detected only in glycoconjugates, with highest signal in fractions 13 and 15.

Supplementary Figure 3. Assessing PG sizes and multivalency by SEC. (A) SEC of SDC1 samples (top, Fig 1C) and dextran standards (bottom), with elution peaks annotated for the latter. (B) calibration curve created from dextran standards, using log₁₀ molecular weight (MW, kDa). (C) Tabulated data from B. (D) Estimated sizes of SDC1 core protein and glycoconjugates calculated using dextran SEC standards.

Supplementary Figure 4. Confirmation of SDC1 alkyne occupancy upon conjugation with azHEP. (A) Graphical depiction of experiment. SDC1₃₇ or SDC1_{45,47} (depicted) were reacted with either azido-heparin (left) or heparin (non-functionalized, right) for 2 h at 37°C, before the addition of azido-TMR (blue). If alkyne sites are occupied by azido-heparin, no labelling with azido-TMR will occur. (B) SDS-PAGE analysis of click reaction products. Positive TMR staining (blue) is detected only in SDC1 samples treated with heparin.

Supplementary Figure 5. Pilot assays for AlphaScreen binding to integrin $\alpha_v\beta_3$. **(A)** Pilot assay of AlphaScreen assay with titrated biotinylated FGF2 and SDC1_{37,45,47HEP}. **(B)** AlphaScreens performed with SDC1₄₇ (left) and SDC1_{47HEP} (right) show no discernible binding to biotinylated $\alpha_v\beta_3$ integrin. Positive control bead (biotinylated, poly-His tagged peptide, purple) included to confirm successful assay.

Supplementary note 1

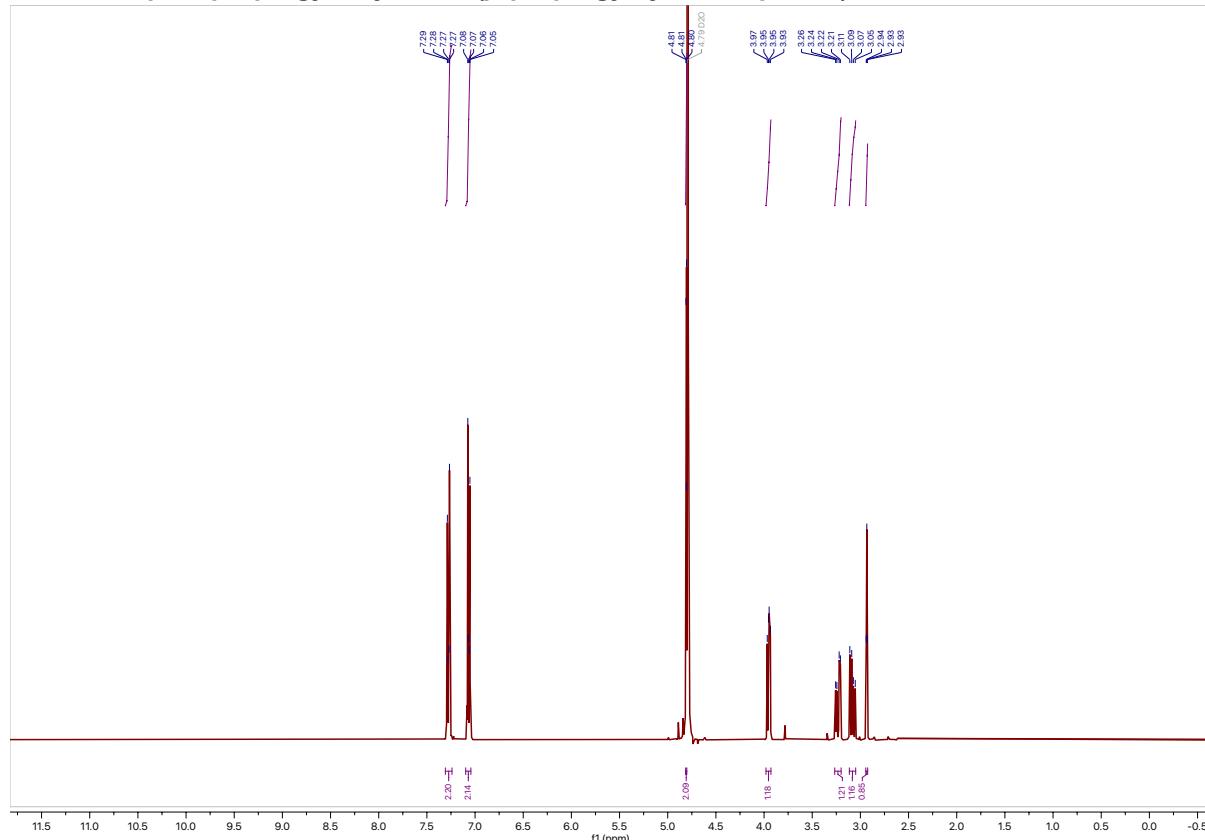

Synthesis and characterisation of chemical structures

NMR/Chemistry protocols. All the starting material chemicals were purchased from commercial suppliers (Carbosynth, Sigma Aldrich, Flurochem and Acros) and used without further purification. Unless otherwise stated, all reactions containing air- and moisture sensitive reagents were carried out under an inert atmosphere of nitrogen in oven-dried glassware with magnetic stirring. All reactions were monitored by thin-layer chromatography (TLC) on Merck DC-Alufolien plates precoated with silica gel 60 F254. TLC plates were visualized with UV-light (254 nm) and stained with H₂SO₄ (8 %). Silica gel column chromatography was carried out using Davisil silica gel or with automated flash chromatography suite (Biotage SP4 HPFC). ¹H NMR (400 or 600 MHz), ¹³C NMR (125 or 151 MHz) spectra were recorded on Bruker AVANCE NEO 400 and 600 MHz instrument at 25 °C in chloroform (CDCl₃), MeOH (CD₃OD), and water (D₂O).

Preparation of *p*-propargyl tyrosine (pPY, 1) unnatural amino acid. The synthesis of pPY was completed in three steps starting from commercially available *N*-Boc tyrosine, following the procedures outlined by Deiters et al¹. Briefly, *N*-*tert*-butoxycarbonyltyrosine (2 g, 7 mmol, 1 eq.) in DMF (15 mL) was slowly reacted with propargyl bromide (2.1 mL, 21 mmol, 3 eq., 80% toluene) overnight at RT. Following extraction with water and Et₂O, the combined organic layers were concentrated to yield the di-esterified product, a yellow oil, which was directly used in the next step. To a cooled (0 °C) solution of the crude material in 60 mL methanol was slowly added a solution of 5 M HCl/MeOH until complete product formation. The solution was allowed to warm to room temperature and volatiles were removed to yield the propargyl ester as a yellow solid. The resulting product was dissolved in a mixture of 2 M NaOH and MeOH for 2 hr at RT. The pH was adjusted to 7 and the mixture was kept at 4 °C overnight. The resulting precipitate was washed with ice-cold water and dried *in vacuo* to yield a beige solid (1.2 g, 78% isolated yield,).

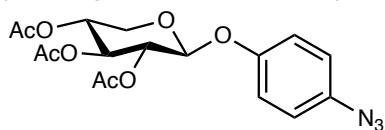

¹H NMR of para propargyl-L-tyrosine (*p*-propargyl tyrosine, pPY, 1).

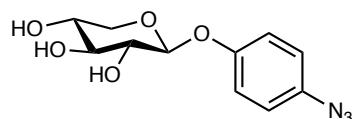

¹H NMR (400 MHz, D₂O) δ 7.31 – 7.24 (m, 2H), 7.09 – 7.04 (m, 2H), 4.81 (d, *J* = 2.4 Hz, 2H), 3.95 (dd, *J* = 7.8, 5.2 Hz, 1H), 3.23 (dd, *J* = 14.7, 5.2 Hz, 1H), 3.08 (dd, *J* = 14.7, 7.8 Hz, 1H), 2.93 (t, *J* = 2.4 Hz, 1H).

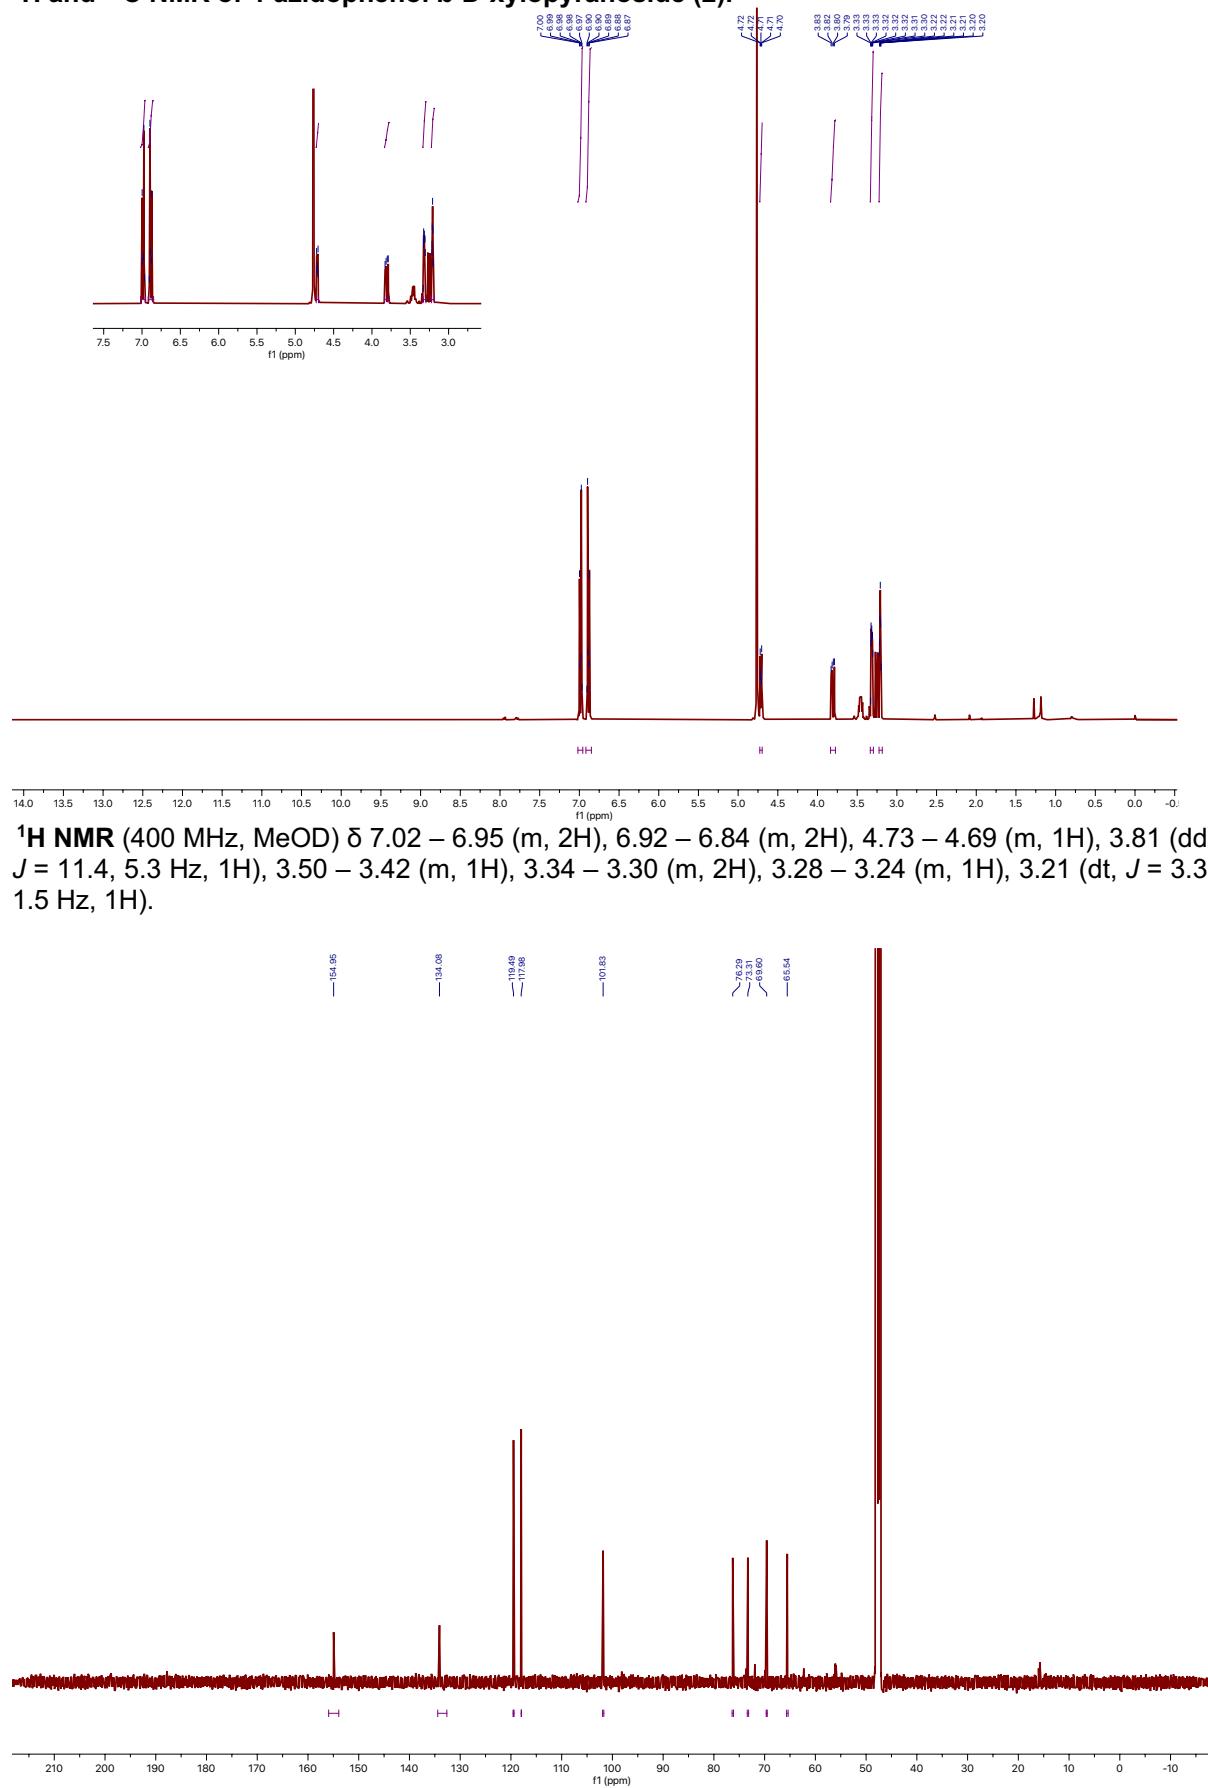

Preparation of azidoxyloloside 2. 1-bromo-xyloside² (1.78 g, 5.25 mmol, 1 eq) in CH₂Cl₂ (50 mL) was added to a stirred solution of 4-azidophenol (851 mg, 6.3 mmol, 1.2 eq) in 1M K₂CO₃ (50 mL). Upon addition of tetrabutylammonium bromide (3.39 g, 10.5 mmol, 2 eq), the reaction mixture was heated to 40 °C for 3 hr before being allowed to cool to RT and quenched with H₂O (200 mL). The resulting layers were separated, and the aqueous layer was extracted with CH₂Cl₂ (5 X 100 mL). The combined organic fractions were dried over Na₂SO₄, filtered, and evaporated under reduced pressure. The crude residue was subsequently purified by flash column chromatography (Hex/EtOAc, 3:7 → 1:9, v/v) to furnish the peracetylated azidophenolxyloside as a solid (640 mg, 1.63 mmol, 31%). R_f: 0.32 (Hex/EtOAc; 3:7, v/v).

Peracetylated azidophenolxyloside (412 mg, 1.05 mmol, 1 eq) was dissolved in anhydrous MeOH (1.5 mL) and Na₂CO₃ (33 mg, 0.315 mmol, 0.3 eq) was added in 1 portion. The resulting mixture was stirred at RT for 4 hr. Upon completion of the reaction, DOWEX® H⁺ resin was added to quench solution. The suspension was filtered and concentrated *in vacuo* before being purified by flash column chromatography (Hex/EtOAc; 1:9 → 100%, v/v) to give **2** as an amorphous solid (259 mg, 0.97 mmol, 92%). Rf:0.27 (Hex/EtOAc; 1:9). **HRMS** (ESI): *m/z* calcd. for C₁₁H₁₂N₃O₅: 266.0777 [M - H]⁻, found 266.0772

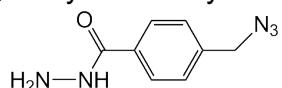

^1H and ^{13}C NMR of 4-azidophenol β -D-xylopyranoside (2).

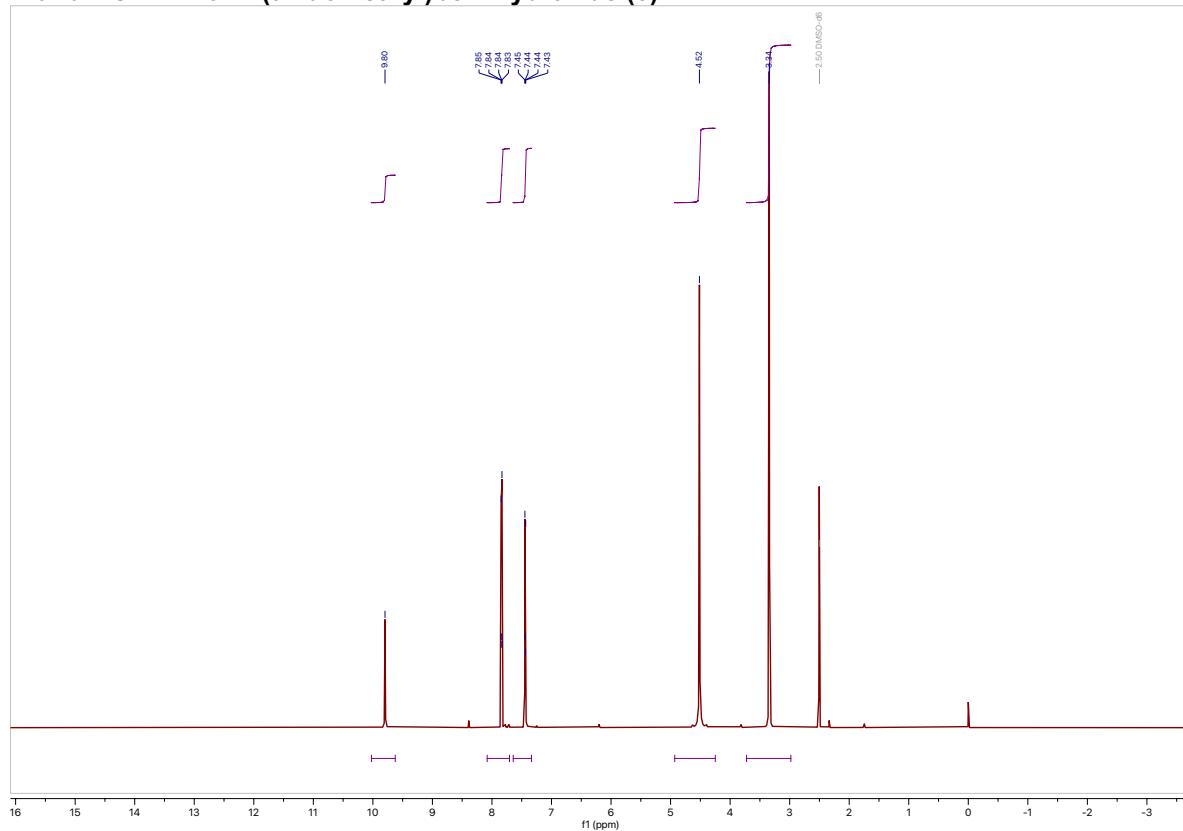

^1H NMR (400 MHz, MeOD) δ 7.02 – 6.95 (m, 2H), 6.92 – 6.84 (m, 2H), 4.73 – 4.69 (m, 1H), 3.81 (dd, $J = 11.4, 5.3$ Hz, 1H), 3.50 – 3.42 (m, 1H), 3.34 – 3.30 (m, 2H), 3.28 – 3.24 (m, 1H), 3.21 (dt, $J = 3.3, 1.5$ Hz, 1H).

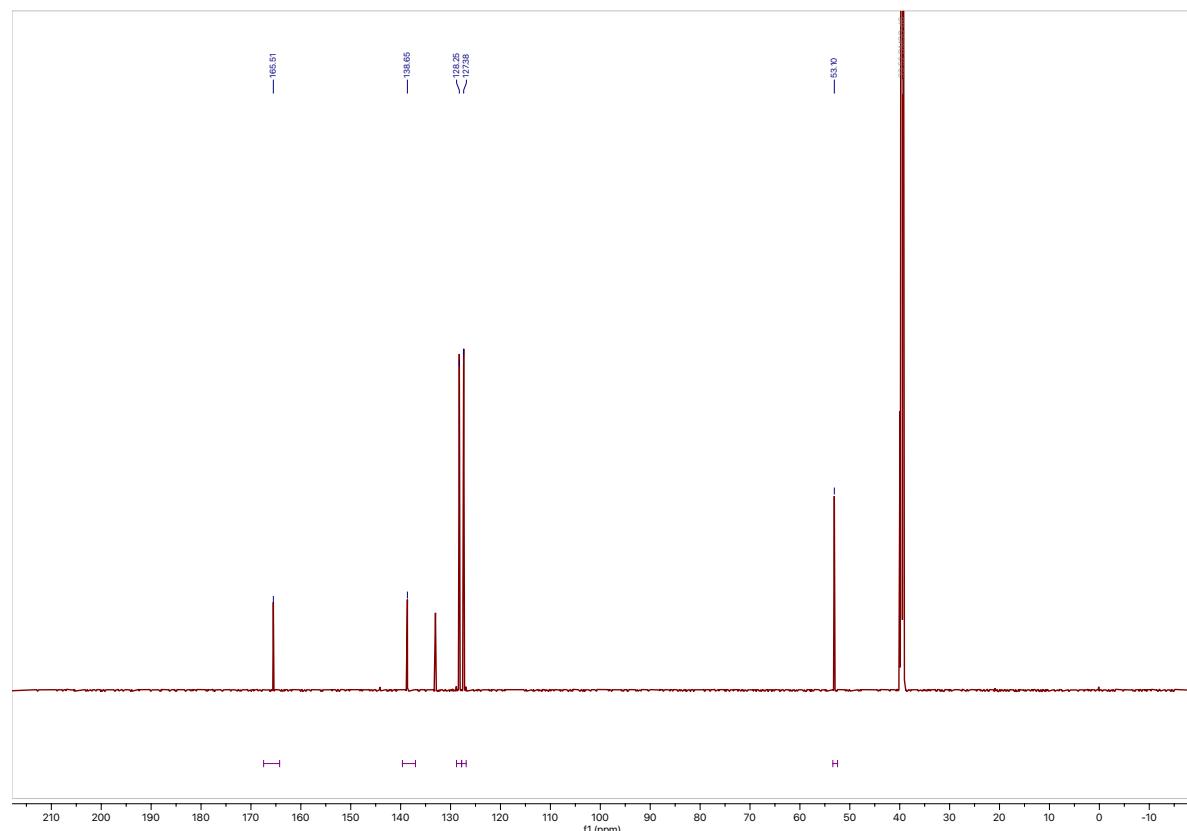

Preparation of 4-(azidomethyl)benzhydrazide (3). Starting from commercially available methyl 4-(bromomethyl)benzoate, the linker 4-(azidomethyl)benzhydrazide was synthesized following a two-step procedure³. Briefly, methyl 4-(bromomethyl)benzoate (4 g, 17.5 mmol, 1 eq) was reacted with NaN₃ (3.4 g, 52.3 mmol, 3 eq) in DMF (60 mL) overnight at 75 °C. Following extraction with H₂O and EtOAc, the organic layer was evaporated under vacuum to yield an oil which was used without further purification. The crude material was dissolved in EtOH (60 mL) and refluxed with hydrazine monohydrate (6.8 g, 136 mmol, 7 eq) for 14 hr. Solvent was removed under vacuum. The resulting solid was recrystallized from 2:1 EtOH and EtOAc and washed with ice cold H₂O to yield a fluffy white solid (1.5 g, 45%).

¹H and ¹³C NMR of 4-(azidomethyl)benzhydrazide (3).

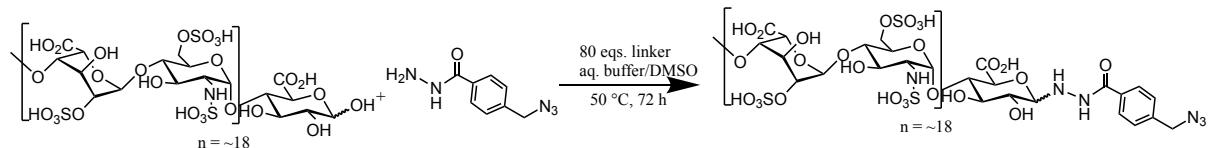

¹H NMR (600 MHz, DMSO) δ 9.79 (s, 1H), 7.93 – 7.77 (m, 2H), 7.54 – 7.32 (m, 2H), 4.51 (s, 4H).

¹³C NMR (151 MHz, DMSO) δ 165.51, 138.65, 128.25, 127.38, 53.10.

Preparation of azido-heparin (azHEP). We followed a previously published procedure for the synthesis of azide-modified GAGs³. Heparin (121.3 mg in 1075 μ L aqueous buffer, 100 mM sodium acetate, 100 mM aniline, pH 5.5) was mixed with 615 μ L of 4-(azidomethyl)benzhydrazide (1.05 M in DMSO (123 mg, 80 eqs). The mixture was protected from light and heated (50 °C, 72 hr). The reaction was diluted into 40 mL of PBS, filtered, (0.45 μ m) and dialyzed in 10 mM NH₄CO₃H (48 hr, exchange buffer 3 times). The sample was lyophilized for a yield of 66.8% (81.0 mg). Conjugation of 4-(azidomethyl)benzhydrazide to heparin was verified by the presence of two broad peaks in the aromatic region of the ¹H NMR spectrum, and integration of anomeric and aromatic ¹H NMR signals yielded a ratio of 1:0.048 (anomeric:aromatic), in agreement with the published procedure.

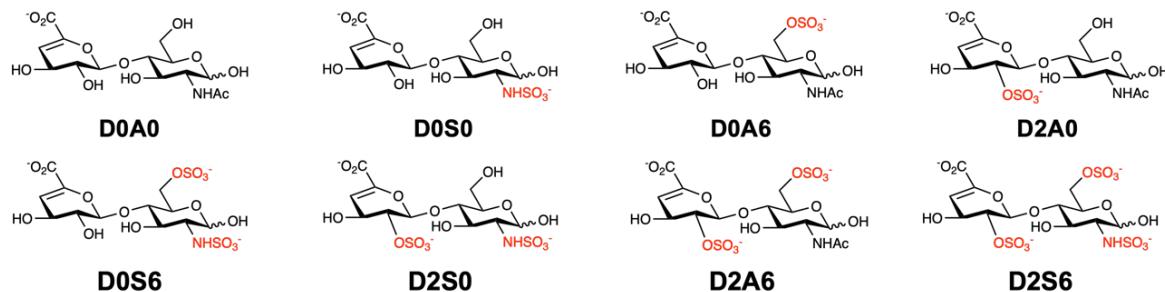

Supplementary Note 2:

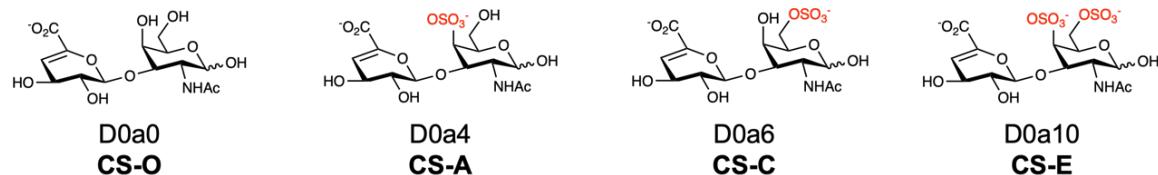

Chemical structures of heparan sulfate and chondroitin sulfate disaccharides.

Depicted chemical structures were generated by enzymatic digestion of HS and CS GAG chains, respectively, and purchased commercially as disaccharide standards for analyses from Iduron (UK, distributed by Galen Laboratory Supplies).

Heparan sulfate (HS) disaccharides:

Chondroitin sulfate (HS) disaccharides:
