

**Supplementary Information for:**

**Poly(ADP) ribose polymerase promotes DNA polymerase theta-mediated end joining by activation of end resection**

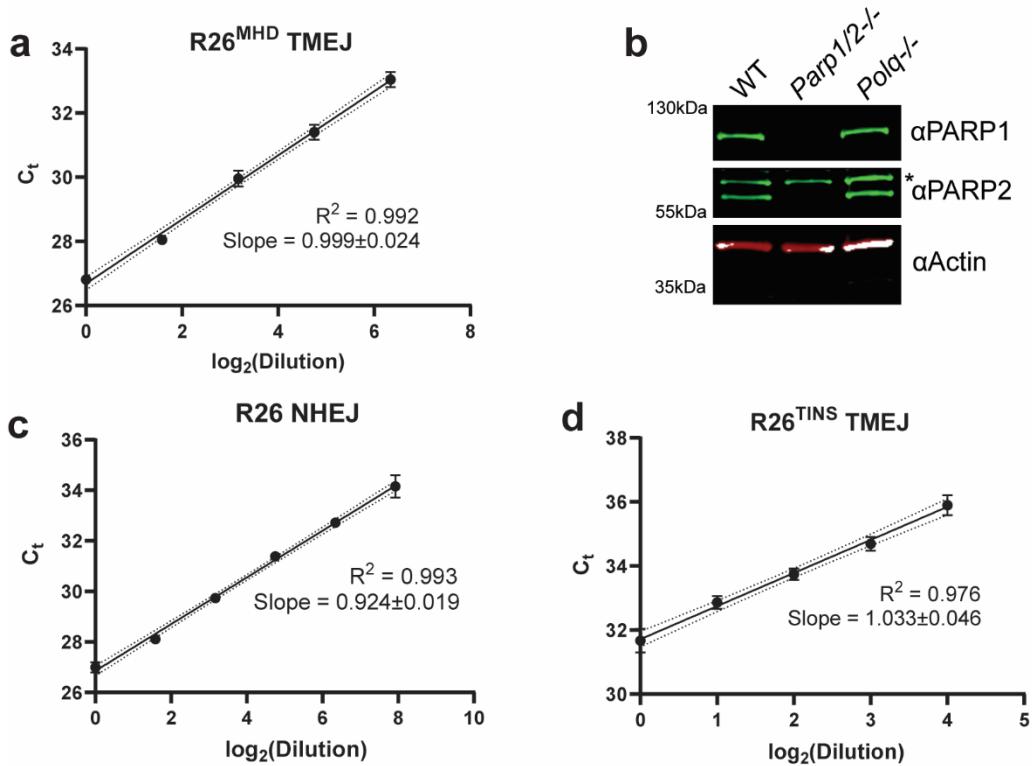

Megan Luedeman, Susanna Stroik, Wanjuan Feng, Adam J Luthman, Gaorav P Gupta, and Dale A Ramsden

## Supplementary Figures

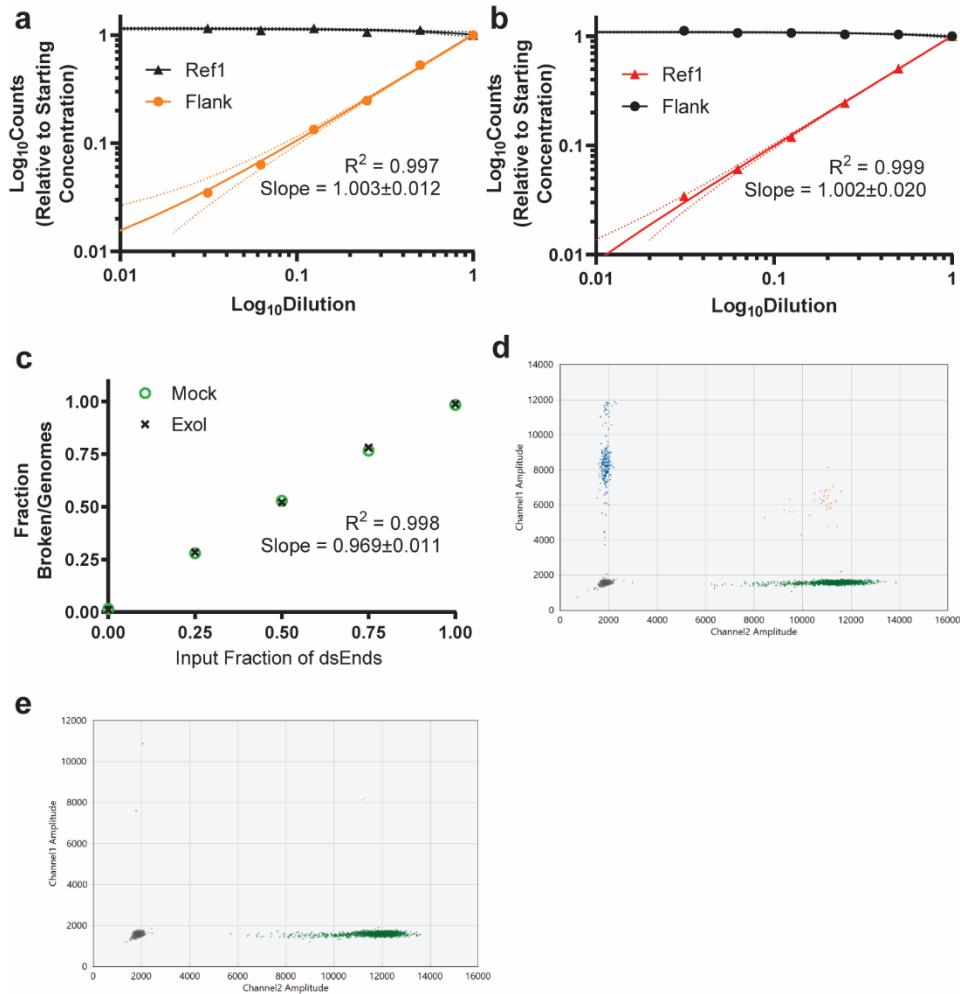

**Supplementary Figure 1 Validation of linearity, limit of detection, and independence of multiplexed qPCR for extrachromosomal repair**

**a)** Cycle thresholds (C<sub>t</sub>) after qPCR of the TMEJ extrachromosomal (EC) amplicon (blue) serially diluted in DNA containing constant amounts of the NHEJ EC amplicon (black); data shown are mean  $\pm$  SD (n=3). The slope, coefficient of determination ( $R^2$ ), fitted line (solid blue line), and 95% confidence intervals (dashed blue lines) after simple linear regression of TMEJ data are noted. **b)** Cycle thresholds (C<sub>t</sub>) after qPCR of the NHEJ EC amplicon (green) serially diluted in DNA containing constant amounts of the TMEJ EC amplicon (black); data shown are mean  $\pm$  SD (n=3). The slope, coefficient of determination ( $R^2$ ), fitted line (solid green line), and 95% confidence intervals (dashed green lines) after simple linear regression of NHEJ data are noted. **c)** Box (interquartile range) and whisker (upper and lower extremes) plot of the non-normalized EC joining efficiency of the NHEJ substrate in vehicle or olaparib treated WT MEFs or Polq<sup>-/-</sup> MEFs as a fraction of the efficiency in vehicle-treated WT cells for all EC trials (WT DMSO n=15; WT 10µM Olaparib n=12; Polq<sup>-/-</sup> n=15). Statistical significance of differences, relative to WT DMSO, was determined by one-way ANOVA (NS, p>0.43, not significant).

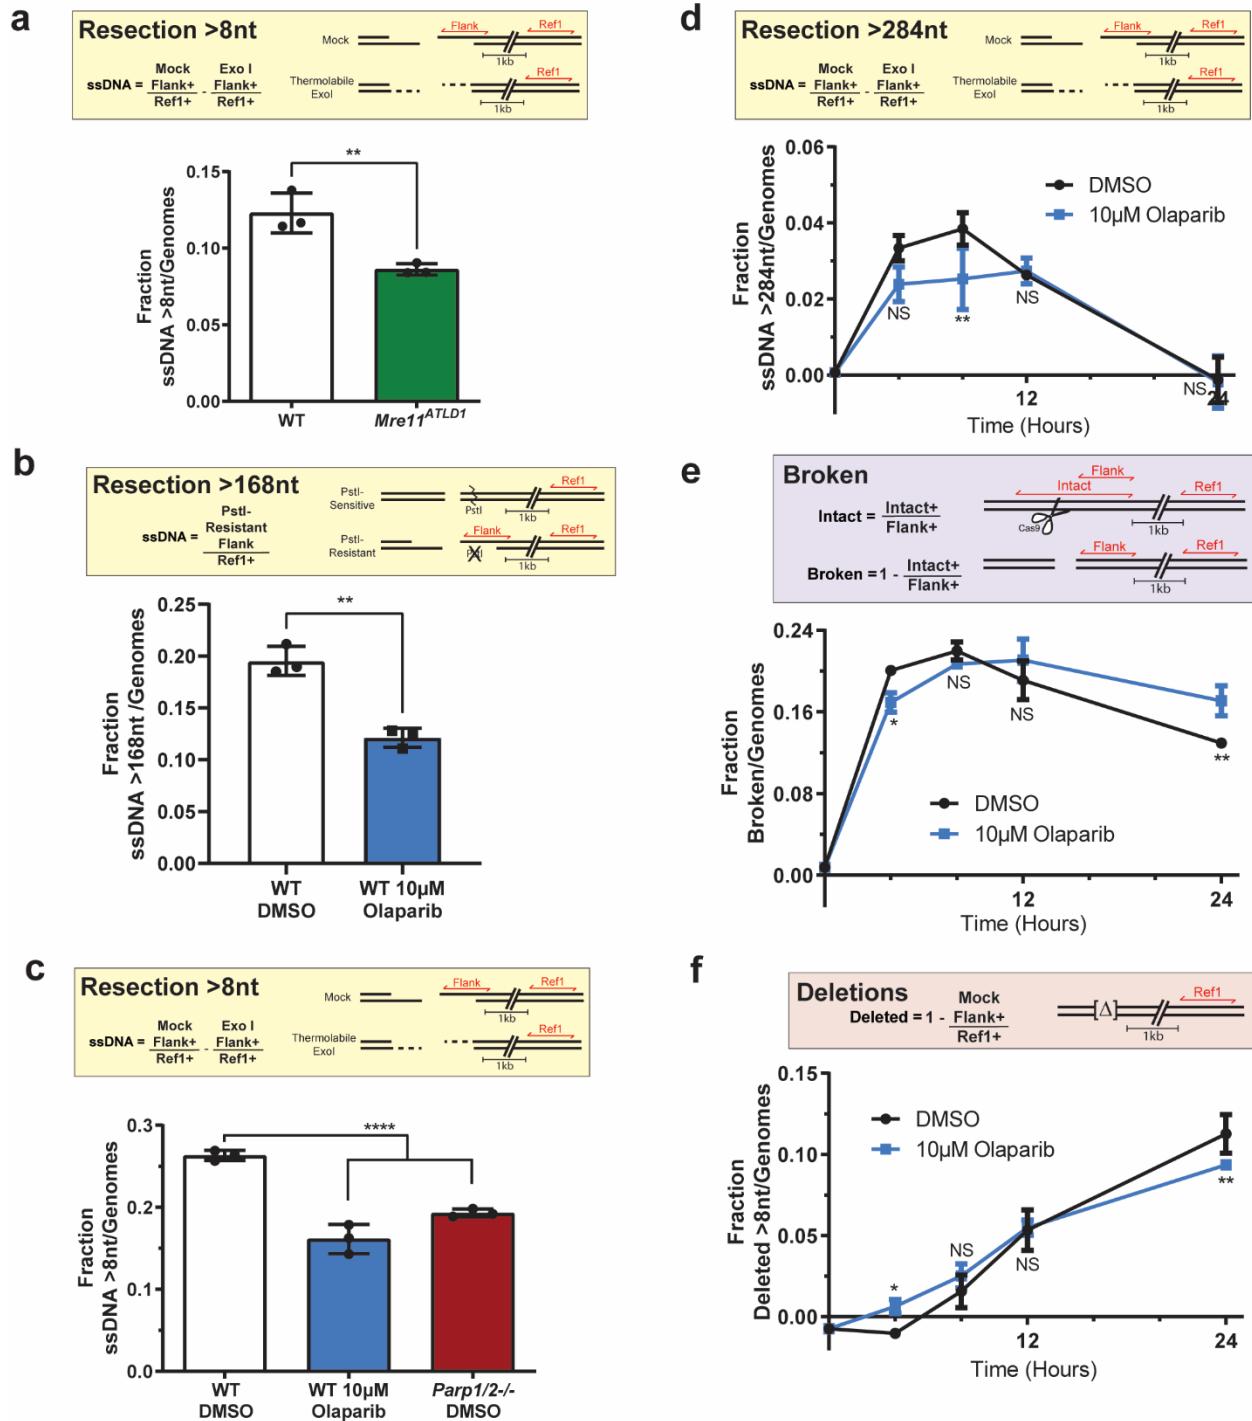

**Supplementary Figure 2 Validation of linearity and limit of detection of qPCR for chromosomal repair**

**a)** Cycle thresholds (C<sub>t</sub>) after qPCR of R<sub>26</sub><sup>MHD</sup> TMEJ generated from WT MEFs transfected with Cas9-gRNA after serial dilution into genomic DNA from MEFs with uncut DNA. Data shown are mean ± SD (n=3); the slope, coefficient of determination (R<sup>2</sup>), fitted line (solid line), and 95% confidence intervals (dashed lines) after simple linear regression are noted. **b)** Immunoblot for PARP1 (116 kilodaltons; kDa), PARP2 (62kDa), and actin (42kDa, loading control) in WT, *Parp1/2-/-*, and *Polq-/-* MEFs (n=2). **c)** Cycle thresholds (C<sub>t</sub>) after qPCR for R<sub>26</sub> NHEJ generated from WT MEFs transfected with Cas9-gRNA after serial dilution into genomic DNA from MEFs with uncut DNA. Data shown are mean ± SD (n=3); the slope, coefficient of determination (R<sup>2</sup>), fitted line (solid line), and 95% confidence intervals (dashed lines) after simple linear regression are noted. **d)** Cycle thresholds (C<sub>t</sub>) after qPCR of R<sub>26</sub><sup>TINS</sup> TMEJ generated from WT MEFs transfected with Cas9-gRNA after serial dilution into genomic DNA from MEFs with uncut DNA, after correction using C<sub>t</sub>s for Ref2 (Supplementary Table 3). Data shown are mean ± SD (n=3). The slope, coefficient of determination (R<sup>2</sup>), fitted line (solid line), and 95% confidence intervals (dashed lines) after simple linear regression are noted.

**Supplementary Figure 3 Validation of linearity, limit of detection, and independence of multiplexed ddPCR**

**a)** Flank counts, relative to the starting concentration, in samples with the flank control (ssDNA control; Supplementary Table 3) serially diluted in DNA with a constant amount of the Ref1 control. The slope, coefficient of determination ( $R^2$ ), fitted line (solid orange line), and 95% confidence intervals (dashed orange lines) after simple linear regression are noted. **b)** Ref1 counts, relative to the starting concentration, in samples with the Ref1 control serially diluted in DNA with a constant amount of the flank control. The slope, coefficient of determination ( $R^2$ ), fitted line (solid red line), and 95% confidence intervals (dashed red lines) after simple linear regression are noted. **c)** Fraction of broken chromosomes, relative to the number of genomes determined by Flank counts, in samples mock (green circles) or Exol-treated (black x's) with increasing levels of chromosomes broken by digestion with XbaI (cuts adjacent to Cas9 site; input dsEnds). **d and e)** Example 2D-plot of the ssDNA control and Ref1 multiplexed-ddPCR in mock- (**d**) and Exol-treated (**e**) samples. Blue points (channel 1/FAM) are droplets positive for only the ssDNA control, and green points (channel 2/HEX) are droplets positive for only Ref1. Droplets positive for both are orange, and double negative droplets are grey.

**Supplementary Figure 4 PARPi does not affect broken chromosomes or deletions >8bp**

**a)** Fraction of chromosomes with ssDNA >8nt after 4 hours in WT or  $Mre11^{ATLD1}$  MEFs (n=3). Data shown are mean  $\pm$  SD, and significance of difference determined by unpaired, two-tailed t-test (\*\*p=0.0092). **b)** Fraction of ssDNA >168nt after 4 hours in WT MEFs treated with DMSO or 10 $\mu$ M olaparib as determined by PstI resistance. Data shown are mean  $\pm$  SD, and significance of difference determined by unpaired, two-tailed t-test (\*\*p=0.0016). **c)** Fraction of chromosomes with ssDNA >8nt after 4 hours in WT MEFs treated with DMSO or 10 $\mu$ M olaparib

or *Parp1/2*<sup>-/-</sup> MEFs (n=3). Data shown are mean ± SD, and statistical significance determined by one-way ANOVA (\*\*\*\*p<0.0001). The same biological replicates were used in b and c. **d-f**) Fraction of ssDNA >284nt generated by long-range 5'-to-3' resection (**d**), broken chromosomes (**e**) or deletions >8bp (**f**) in WT MEFs treated with DMSO (black) or 10μM olaparib (blue) over 24 hours. Time course data shown are mean ± SD of one biological replicate and four (d) or three (e and f) technical replicates; these data were generated from the same biological replicate used in Figure 5. Statistical significance of difference, relative to WT DMSO, was determined by one-way ANOVA (\*p<0.03; \*\*p<0.01; NS, p>0.09, not significant). Colored boxes refer to Figure 5a. Amplicons used for ddPCR are shown in red; Δ indicates deletion repair products. The number of genomes in each PCR was determined by a reference amplicon ~1kb (Ref1) from the cut site.

## Supplementary Tables

**Supplementary Table 1**

Gene	gRNA sequence + PAM	Chr. location
<i>Polq</i>	ATACGGGAGCGG <u>A</u> TGTGTC <u>CAGG</u>	16: 36,906,960
<i>Polq</i>	CAGTTCAAGCT <u>G</u> AGAGT <u>A</u> GT <u>CGG</u>	16: 36,906,888
<i>Parp1</i>	CTCAACATCAGGCTGCCGG <u>A</u> TGG	1: 180,401,284
<i>Parp2</i>	CTTCAAGAGCGATGGCGCC <u>CGG</u>	14: 51,045,394

gRNA sequences + PAM (underlined) and sequence location in the mouse genome for sites mutated to knock out *Polq* in KPB13 cells and knock out *Parp1* and *Parp2* in MEFs.
