Supplementary Materials and Methods

In order to test the hypothesis that *Drosophila* phenotype (DP) classes are not well connected with specific human phenotype classes, we define MIS-HP. MIS-HP is the most informative superclass from human phenotypes to a certain class. Let C be a *Drosophila* phenotype class, we define MIS-HP for this class as shown in equation 1. Then we calculate the absolute difference between the information content of DP and its MIS-HP, we will use ($\text{sum}\Delta_G$) to refer to some of this difference for all the annotations of a gene. Let G_i be the i^{th} annotation for a gene, we calculate $\text{sum}\Delta_G$ as shown in equation 2.

$$\text{MIS-HP}(C) = \max_{P \in \text{Superclasses}(C) \cap HP} IC(P) \quad (1)$$

$$\text{sum}\Delta_G = \sum_i |IC(G_i) - IC(\text{MIS-HP}(G_i))| \quad (2)$$

$$\text{avg}\Delta_G = \frac{\sum_i |IC(G_i) - IC(\text{MIS-HP}(G_i))|}{n} \quad (3)$$

To visualize the difference between the associated genes and the non-associated genes, we calculate $\text{avg}\Delta_G$ as the average of the absolute difference between DP and its MIS-HP. Let n be the number of annotations a gene have, equation 3 shows how we calculate $\text{avg}\Delta_G$. Figure S2 shows the density histogram for the $\text{avg}\Delta_G$ for disease-associated genes and non-disease associated genes.

We compare the list of $\text{sum}\Delta_G$ for the disease-associated genes and the non-disease-associated genes. This comparison is done using a t-test and the result shows that $\text{sum}\Delta_G$ for the disease-association genes is significantly higher than the non-disease-associations p-value ($p = 4 \times 10^{-61}$), and mean 44.5 for disease-associated genes and mean 13.9 for non-disease-associated genes.
