This supplementary material has been provided by the authors to give readers additional information about their work.

eMethod: Simulations to recapture Kaplan-Meier survival curves of KEYNOTE 045 and CheckMate 017/057

eFigure 1 (A) and (B) show survival curves generated from simulated data based on KEYNOTE 045 of chemotherapy ($n_0 = 272$) versus pembrolizumab ($n_1 = 270$) for OS or PFS of patients with advanced UC (1). OS or PFS probabilities at 4-month intervals were extracted from the KM survival curves (Reference 1, Figure 1A-B), and the proportions of long-term responders were assumed to be 0.13 (0.01) and 0.22 (0.11) in the chemotherapy and pembrolizumab arms, respectively. We fitted mixture cure models with Weibull distributions to the extracted probabilities by the nonlinear least-squares method, and we obtained two Weibull distributions with a common shape parameter of 1.133 (0.690) and different scale parameters of 0.697 (0.312) and 0.789 (0.235) for the two arms, respectively. Accordingly, event times were generated from mixture cure models with the estimated Weibull distributions and the proportions of long-term responders. Moreover, we assumed the same uniform distribution Uniform(2, 3) of censoring time for both arms. Then, we obtained the simulated data and produced the unadjusted KM curves as shown in eFigure 1A-B.

Similarly, eFigure 1 (C) and (D) are simulations from the CheckMate 017/057 trial of docetaxel (n_0 = 427) versus nivolumab (n_1 = 427) for OS or PFS of patients with advanced NSCLC (2). OS or PFS probabilities at 6-month intervals were extracted from the KM survival curves (Reference 2, Figure 1A for OS and Figure 2A for PFS), and the proportions of long-term responders were assumed to be 0.02 (0.00) and 0.11 (0.07) in the docetaxel and nivolumab arms, respectively. Following the same procedure described as above, we obtained two Weibull distributions with a common shape parameter of 0.939 (0.638) and different scale parameters of 0.931 (0.308) and 1.120 (0.350) for the two arms, respectively. Also, we assumed the same uniform distribution Uniform(5, 6.5) of censoring time for both arms. Thus, we obtained the simulated data and the unadjusted KM curves as shown in eFigure 1C-D.

eFigure 3. Subgroup analyses of overall survival. (A) NSCLC, (B) UC, (C) melanoma. Forest plots of Cox HRs (HR), Cox-TEL HRs (ST-HR), and LT-DPs illustrate overall survival endpoints of included studies before and after Cox-TEL adjustment. Individual and pooled HRs, ST-HRs, and LT-DPs are shown with 95% CI. Pooled endpoints are meta-analysis results. The weight for each study is inversely proportional to the within-study variance of log(HR) plus the between-studies variance. Abbreviations: Nivo: nivolumab; Pembro: pembrolizumab; Atezo: atezolizumab; Ipi: ipilimumab; Dac: dacarbazine; ICC: investigator's choice chemotherapy (dacarbazine or carboplatin plus paclitaxel).
