Web Appendix

Methods:

Study Population:

The Women's Lifestyle Validation Study is one of the three components of the Multi-Cohort Eating and Activity Study for Understanding Reporting Error (MEASURE)(16), which was conducted to investigate the measurement error associated with self-reported physical activity and dietary assessments. The study was conducted within the NHS and NHSII between 2010 and 2012. The NHS cohort was initiated in 1976 when 121,701 US registered female nurses, aged 30-55 years were recruited. The NHS-II cohort was initiated in 1989 when 116,429 US female nurses, aged 25-42 years were enrolled. Participants in both cohorts have completed mailed questionnaires every two years about their medical history and lifestyle factors. Invited participants were a random sample of NHS and NHSII participants who had no history of coronary heart disease, stroke, cancer, or major neurological disease, completed the 2006/7 food frequency questionnaire, had previously provided blood samples, had access to broadband internet, and were not planning to make any substantial changes in their diet or physical activity. A total of 5,503 women were invited to participate; 851 consented to participate, and 796 women were enrolled due to budgetary constraints (Web Figure 1). This study was approved by the human subject committees of the Harvard T.H. Chan School of Public Health and Brigham and Women's Hospital.

Physical Activity Assessments:

To represent the one-year time frame of the PA questionnaire, data were collected over approximately 15 months with the order of measurements varied (Figure 1). This included two self-administered PAQs, four ACT24s, one DLW measurement (repeated among 90 women), two one-week accelerometer measurements, and four RPR measurements. To avoid artificial high correlations between the different assessment methods, a two-

week spacing was implemented between the PAQ and ACT24, accelerometer and ACT24, and PAQ and accelerometer. The DLW measurement and one of the accelerometer measurements were designed to occur during the same phase (three-month period) of the study, but not during the same week in order to avoid artificial high correlations.

Physical activity questionnaire (PAQ)

In addition to type of activities, participants reported their walking pace: easy (< 2 miles/hour), normal (2 – 2.9 miles/hour), brisk (3 – 3.9 miles/hour), or very brisk/striding (\geq 4 miles/hour), and number of flights climbed daily (no flights, 1-2, 3-4, 5-9, 10-14, \geq 15 flights). Data on sedentary behaviors were also collected and included sitting at work or commuting, sitting at home while watching TV/VCR/DVD, and other sitting at home (e.g. desk, eating, computer).

Activities were grouped by intensity as follows: vigorous PA (\geq 6 MET: jogging, running, high-intensity bicycling, lap swimming, and tennis, squash/racquetball, stairs), moderate PA (3-5.9 MET: walking \geq 2 mph, low- to moderate-intensity bicycling, lap swimming, and tennis, other aerobic exercise, moderate/heavy outdoor work, weightlifting), and moderate to vigorous intensity PA (MVPA; \geq 3 MET). Total activity included light (<3 MET) and MVPA.

Activities Completed Over Time in 24 hours (ACT24)

For overlapping activities, the tool allowed participants to indicate their primary activity during that period. Data on posture and level of energy expenditure were collected and behaviors were categorized as active (standing upright or activity requiring a high level of energy expenditure \geq 2 MET) or sedentary (sitting, reclining, or lying down activity requiring a low level of energy expenditure < 2 MET). An energy expenditure score (MET-hours/week) was computed based on the MET score associated with each activity which was derived from the 2011 Compendium of Physical Activity (18) multiplied by the time spent on each activity.

Accelerometer

Participants were instructed to wear the monitor on the hip for seven days during all waking hours, except when bathing or swimming, and record the days the monitor was worn. Epoch length of 1 second was set, and we used data based on the triaxial vector magnitude. Data on total activity counts (TAC) per day were used to determine the total volume of physical activity. Intensity was defined according to the following thresholds: <200 counts/minute for sedentary behavior, 200-2689 counts/minute for light intensity, 2690-6166 counts/minute for moderate intensity, and ≥ 6167 counts/minute for vigorous intensity. Time spent in each intensity category was summed up for every minute per day. For sedentary behavior, time spent in ≥ 15 -minute bouts was also examined.

Non-wear time was defined as 60 minutes or more with consecutive zero accelerometer counts, allowing up to two minutes with limited movement (< 200 counts per minute, the threshold for sedentary time using triaxial counts) (1, 2). Mean daily time in intensity-specific categories was calculated across all valid wear days, then divided by 60 to get the number of hours per day. To predict METs from triaxial counts, we used the equation METs = 0.000863* (activity counts from all 3 axes) + 0.668876. For each minute of non-wear time or when triaxial counts were < 100 per minute, a value of 1 MET was assigned. The computed METs were summed over all minutes to get total energy expenditure in MET-min/day, which was then divided by 60 to compute MET-hours/day. Two 1-week accelerometer measurements were taken for each participant which were spaced at least 6 months apart.

Statistical Analyses

Deattenuated correlation coefficients and their 95% CIs were computed to account for within-person variation and number of repeated measurements of the reference method using the formula: $r_c = r_o \sqrt{1 + \lambda/k}$ where r_c is the deattenuated correlation coefficient, r_o represents the observed correlation coefficient, λ is the ratio of within- to between-person variation, and k is the number of replicates of the reference method.

Method of Triads:

The method of triads was used to estimate the correlation of each assessment method with the latent true physical activity level. In the method of triads, we assumed that the random errors of the physical activity assessment methods were uncorrelated because these methods were administered in random order and not close in time to avoid spuriously high correlations, and the different assessment methods rely on different sources of information. We also assumed that positive linear correlations existed between the assessment methods and the true physical activity levels (3). In this method, we checked for Heywood cases which usually occur when the estimated validity coefficients are >1 or inestimable (4).
