

◆ HIBISCUS I/II ◆ HICKORY

Positive outcome probability (90% CI)

Figure S2. Forest plots for all final models based on data from the induction phases of HIBISCUS I/HIBISCUS II and HICKORY. Diamonds and error bars depict the median and 90% confidence interval, respectively, for the outcome proportion derived from a 200-sample bootstrap per model. For each covariate/endpoint, the proportion is presented assuming typical values for all other covariates. A typical subject was treated with etrolizumab with a median exposure of 3.65 $\mu\text{g/mL}$ at week 4 of induction, never smoked and had baseline levels for albumin, CRP, FeCal, and MCS score of 41 g/L, 4.2 mg/L, 1623 $\mu\text{g/g}$, and 9, respectively. perc: percentile; CRP: C-reactive protein; C_{trough} : trough concentration; FeCal: fecal calprotectin; MCS: Mayo Clinic Score.
