## SUPPLEMENTARY APPENDIX

Table S1. Characteristics of the studies included in the meta-analysis.

**Table S2**. Risk-of-bias summary for the studies included in the meta-analysis, using Cochrane risk-of-bias tool ROBINS-I.

**Table S3**. Certainty of evidence and summary effect estimates assessed by GRADE (grading of recommendations, assessment, development, and evaluation) of the study outcomes.

**Table S4**. Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular diseases, according to study characteristics.

**Table S5**. Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular diseases, according to a variety of adjustments.

**Figure S1.** Forest plot of risk ratio of overall cardiovascular and cerebrovascular diseases in women with a history of gestational diabetes mellitus.

**Figure S2.** Forest plot of risk ratio of cardiovascular diseases in women with a history of gestational diabetes mellitus.

**Figure S3.** Forest plot of risk ratio of cerebrovascular diseases in women with a history of gestational diabetes mellitus.

**Figure S4.** Sensitivity analysis using the jackknife approach, (A) overall cardiovascular and cerebrovascular diseases, (B) cardiovascular diseases, (C) cerebrovascular diseases.

**Figure S5.** Sensitivity analysis after excluding the case-control study for the outcome of overall cardiovascular and cerebrovascular diseases.

Figure S6. Sensitivity analysis after excluding the studies without direct information on the risk estimates for the outcome of overall cardiovascular and cerebrovascular diseases.

**Figure S7.** Funnel plot, (A) overall cardiovascular and cerebrovascular diseases, (B) cardiovascular diseases.

**Figure S8.** Forest plot of risk ratio of coronary artery diseases in women with a history of gestational diabetes mellitus.

**Figure S9.** Forest plot of risk ratio of myocardial infarction in women with a history of gestational diabetes mellitus.

Figure S10. Forest plot of risk ratio of heart failure in women with a history of gestational diabetes mellitus.

Figure S11. Forest plot of risk ratio of angina pectoris in women with a history of gestational diabetes mellitus.

**Figure S12.** Forest plot of risk ratio of cardiovascular procedures in women with a history of gestational diabetes mellitus.

Figure S13. Forest plot of risk ratio of overall stroke in women with a history of gestational diabetes mellitus.

**Figure S14.** Forest plot of risk ratio of ischemic stroke in women with a history of gestational diabetes mellitus.

**Figure S15.** Forest plot of risk ratio of hemorrhagic stroke in women with a history of gestational diabetes mellitus.

**Figure S16.** Forest plot of risk ratio of venous thromboembolism in women with a history of gestational diabetes mellitus.

**Figure S17.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to year of publication.

**Figure S18.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to study location.

**Figure S19.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to study design.

**Figure S20.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to source of data.

**Figure S21.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to follow-up duration.

**Figure S22.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to method of ascertainment of gestational diabetes mellitus.

**Figure S23.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to method of ascertainment of cardiovascular and cerebrovascular diseases.

**Figure S24.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to sample size.

**Figure S25.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to number of events.

**Figure S26.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to risk-of-bias (ROBINS-I).

Figure S27. Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to adjustment of

race.

**Figure S28.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to adjustment of smoking.

**Figure S29.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to adjustment of body mass index.

Figure S30. Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to adjustment of socio-economic status.

Figure S31. Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to adjustment of education level.

**Figure S32.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to adjustment of parity.

**Figure S33.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to adjustment of comorbidities.

**Figure S34.** Subgroup analyses of the association between gestational diabetes mellitus and overall cardiovascular and cerebrovascular diseases, according to adjustment of pregnancy complications.

venous thromboembolism	4	1.28 (1.13, 1.46)	serious	not serious	not serious	not serious	none	⊕000 VERY LOW

\*Downgraded by one level if >25% of participants in this comparison were from studies at high risk of bias. †Downgraded by one level if heterogeneity ( $I^2$ ) >50%.

## $\pm$ Downgraded by one level if >25% of included studies were monocenter-based.

§Downgraded by one level if the limits of the 95% CI for risk estimates are wide or cross a minimally important difference of 10% for outcomes (RR 0.9-1.1). #High quality: very confident that the true effect lies close to that of the estimate of the effect; moderate quality: moderately confident in the effect estimate, and the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different; low quality: confidence in the effect estimate is limited, and the true effect could be substantially different from the estimate of the effect; very low quality: very little confidence in the effect estimate, and the true effect is likely to be substantially different from the estimate of effect.

## Appendix S1. Updated Study protocol

#### Title

Association of Gestational Diabetes Mellitus with Overall and Type-Specific Cardiovascular and cerebrovascular Diseases: Systematic Review with Meta-Analysis Involving Over 8 Million Participants

#### **Review question**

The risk of overall and type-specific cardiovascular and cerebrovascular diseases (CCVD) as well as venous thromboembolism in women with a history of gestational diabetes mellitus (GDM).

Searches

EMBASE, PubMed, and Cochrane library from inception to from database inception to 1 November 2021 and updated on 26 May 2022 were performed.

### URL to search strategy.

(gestational diabetes OR gestational diabetes mellitus OR pregnancy diabetes OR pregnancy diabetes mellitus) AND (cardiovascular diseases OR cerebrovascular disorders OR venous thromboembolism OR cardiovascular OR cerebrovascular OR coronary artery disease\* OR coronary heart disease\* OR cardiac OR ischemic heart disease\* OR cardiovascular and cerebrovascular OR myocardial infarction OR heart failure OR angina pectoris OR cerebral OR stroke OR transient ischemic attack OR pulmonary embolism OR deep vein thrombosis)

Condition or domain being studied.

Overall and Type-Specific Cardiovascular and cerebrovascular Diseases

# **Participants/population**

Cohort studies, case-control studies, reporting the relationship between GDM and incident CVD. Studies will be excluded as follows:

- 1) Replicated publications from the same cohort
- 2) Insufficient data
- 3) Case report, editorial, review
- 4) Nonhuman studies
- Intervention(s), exposure(s)

Our intervention of interest is the risk of overall and type-specific cardiovascular and cerebrovascular diseases.

Comparator(s)/control

Control without GDM.

Types of study to be included.

retrospective or prospective cohort studies, or case-control studies.

Context

Main outcome(s)

- 1) The primary outcome was the association of GDM with all CVD, cardiovascular and cerebrovascular diseases.
- 2) The secondary outcomes were the association of GDM with type-specific cardiovascular, cerebrovascular diseases as well as VTE (including deep vein thrombosis and pulmonary embolism).

### **Measures of effect**

Pooled risk ratio

Additional outcome(s).

Not applicable.

Data extraction (selection and coding)

The following data will be independently extracted by two authors by two reviewers (WX and YW) on an excel sheet

- 1) First author, publication year, country/countries, study design, data sources.
- 2) Sample size and time period of observations in the study,

3) patients' demographics and clinical characteristics.

5) Study outcomes including number of patients developing CVD. Risk of bias (quality) assessment

The risk of bias of selected studies was assessed independently by 2 reviewers (WX and YW)

according to the Risk of Bias in Nonrandomized Studies of Interventions (ROBINS-I) tool. In brief, this tool consists of the following seven domains: (1) bias due to confounding; (2) bias due to selection of participants; (3) bias due to exposure assessment; (4) bias due to misclassification during follow-up; (5) bias due to missing data; (6) bias due to outcome assessment; and (7) bias due to selective reporting. For each domain, the reviewer's judgments were rated as low risk, moderate risk, serious risk, critical risk, and no information. Any discrepancies were handled by a senior investigator (ZZ).

#### Strategy for data synthesis.

Extracted data for meta-analysis was performed with Stata Statistical Software version 13.0 and RR statistical language version R 3.6.0. The P-values were two sided with significant level a=0.05. Pooled RRs with 95% CIs were calculated as an effect measure using the random effect models (DerSimonian and Laird method) for determining the relationship between GDM and developing cardiovascular and cerebrovascular events. The HR and IRR were used as good estimators of RR to carry out the statistical estimations. Because the occurrence of CCVD in GDM patients was relatively low, the OR mathematically approximates the RRs. We selected risk estimates from the multivariate models that were fully adjusted for confounders. For the studies that only reported the risk estimates for type-specific CCVD however with absence of an overall CCVD, we summarized type-specific risk estimates by either fixed-effects or random-effects model based on the level of heterogeneity to obtain a combined risk estimates of the study, which was finally entered into the main pooled analysis [15]. The heterogeneity across studies was quantify by  $I^2$ statistic (0-25% represents low heterogeneity, 25-50% moderate heterogeneity, 50-75% substantial heterogeneity, 75-100% high heterogeneity). Potential publication bias was assessed by visualization of funnel plot (≥10 included studies) in combination with both Egger's test and Begg's test.

## Analysis of subgroups or subsets.

To identify the subgroup differences and potential sources of the observed heterogeneity, subgroup analyses were carried out after stratifying for median year of publication (before 2017 vs after 2017), study location (North America vs Europe vs Asia), study design (prospective vs retrospective), source of data (nationwide vs non-nationwide), median follow-up duration (>10 years vs  $\leq$  10 years), method of ascertainment of GDM (diagnostic code vs. self-report vs. oral glucose tolerance test [OGTT]), method of ascertainment of CCVD (diagnostic code vs. others), median sample size ( $\geq$ 100,000 vs < 100,000), number of CCVD events ( $\geq$ 2,500 vs < 2,500), and quality of study (moderate vs serious risk of bias). Meanwhile, to explore whether the association of GDM with CCVD was influenced by potential confounders, we performed additional analyses, stratified by a variety of adjustments, including race, smoking, body mass index, socio-economic status, education level, parity, preexisting comorbidities, the presence of pregnancy complications. A difference between the estimates of these subgroups was considered significant for a P-value less than <0.10. In addition, to assess the role of subsequent diabetes in the association between GDM and CCVD, we further analyzed the risk estimate for CCVD in all GDM patients and GDM patients who did not develop future overt diabetes. To evaluate the robustness of pooled results, sensitivity analyses were conducted by excluding each study one by one, excluding the case-control study and exclusively including the studies with direct risk estimates for overall CCVD.

## Type and method of review

Meta-analysis, Systematic review Language No restriction

Section	Previous Protocol	Publication
Title	Association of Gestational Diabetes Mellitus with Overall and Type-Specific Cardiovascular and cerebrovascular Diseases: Systematic Review with Meta-Analysis	Association of Gestational Diabetes Mellitus with Overall and Type- Specific Cardiovascular and cerebrovascular Diseases: Systematic Review with Meta-Analysis Involving Over 8 Million Participants
Authors	Wenhui Xie, Yu Wang, Shiyu Xiao, Lin Qiu, Yang Yu	Wenhui Xie, Yu Wang, Shiyu Xiao, Lin Qiu, Yang Yu, Zhuoli Zhang
Literature search	A literature search was performed using the electronic databases PubMed, EMBASE and the Cochrane Library from database inception to from inception to 1 November 2021	EMBASE, PubMed, and Cochrane library from inception to from database inception to 1 November 2021 and updated on 26 May 2022 were performed.
Risk of bias appraisal	The Newcastle-Ottawa Scale	Risk of Bias in Nonrandomized Studies of Interventions (ROBINS-I) tool
Strategy for data synthesis		For the studies that only reported the risk estimates for type-specific CCVD however with absence of an overall CCVD, we summarized type-specific risk estimates by either fixed-effects or random- effects model based on the level of heterogeneity to obtain a combined risk estimates of the study, which was finally entered into the main pooled analysis
Strategy for data synthesis	Extracted data for meta- analysis was performed with Stata Statistical Software version 13.0	Extracted data for meta- analysis was performed with Stata Statistical Software version 13.0 and RR statistical language version R 3.6.0.
Analysis of subgroups or subsets	Subgroup analyses were carried out by year of publication, study location, study design, source of data, follow-up duration, diagnosis of GDM, diagnosis	To identify the subgroup differences and potential sources of the observed heterogeneity, subgroup analyses were carried out after stratifying for median

of CVD, sample size and study quality. Moreover, to explore whether the association of GDM with CVD was influenced by potential confounders, we performed additional analyses, stratified by the adjustments, including race, smoking, body mass index, socio-economic status, education level, parity, preexisting comorbidities, the presence of pregnancy complications.	year of publication (before 2017 vs after 2017), study location (North America vs Europe vs Asia), study design (prospective vs retrospective), source of data (nationwide), median follow-up duration (>10 years vs $\leq$ 10 years), method of ascertainment of GDM (diagnostic code vs. self-report vs. oral glucose tolerance test [OGTT]), method of ascertainment of CCVD (diagnostic code vs. others), median sample size ( $\geq$ 100,000 vs < 100,000), number of CCVD events ( $\geq$ 2,500 vs < 2,500), and quality of study (moderate vs serious risk of bias). Meanwhile, to explore whether the association of GDM with CCVD was influenced by potential confounders, we performed additional analyses, stratified by a variety of adjustments, including race, smoking, body mass index, socio-economic status, education level, parity, preexisting comorbidities, the presence of pregnancy complications. A difference between the estimates of these subgroups was considered significant

Domain	Explanation	Judgments
Bias due to confounding	<ul> <li>Is there potential for confounding of the effect of exposure in this study?</li> <li>Did the authors use a multivariable-adjusted analysis method that controlled at least for age, sex, smoking, physical activity, and body mass index?</li> <li>Did the authors avoid adjusting for post-exposure variables?</li> </ul>	Low risk of bias:       No bias expected due to confounding, including time-varying confounding.         Moderate risk of bias:       Confounding is expected: including at least 5 factors of the following factors: age, smoking, body mass index (alternatively weight), comorbidities, maternal parity, race/ethnicity, others (socio-economic status, maternal education) and have been appropriately controlled for in a multivariable-adjusted analysis.         Serious risk of bias:       3-4 above-mentioned factors were measured or appropriately controlled for.         Critical risk of bias:       less than 3 above-mentioned factors were measured or appropriately controlled for         No information:       No information on which confounders have been controlled for.
Bias due to selection of participants	<ul> <li>Was the selection of participants into the study based on participant's characteristics observed after the start of the study/exposure assessment?</li> <li>Do the start of follow-up and the start of exposure coincide for most participants? Were methods used that are likely to correct for the presence of selection biases?</li> </ul>	<ul> <li>Low risk of bias: All participants who would have been eligible for the target study were included in the study (e.g. population-based study without special exclusion criteria).</li> <li>Moderate risk of bias: Selection into the study may have been related to exposure and outcome, e.g., inclusion of GDM women with a family history of type 2</li> <li>diabetes only; or exclusion of women with maternal risk factors (e.g. hypertension, heart disease, renal disease); and the authors used appropriate methods to correct for the selection bias;</li> <li>Serious risk of bias: Selection into the study was related to exposure and outcome (e.g., only participants at higher risk of CCVD were included in the analysis); and this could not be corrected for in the analyses; or the start of follow-up and start of exposure do not coincide and the rate ratio is not constant over time.</li> <li><u>Critical risk of bias:</u> over half of included GDM patients having CCVD at baseline;</li> <li><u>No information:</u> No information is reported about selection of participants into the study.</li> </ul>
Bias due to exposure assessment	<ul> <li>Were exposure groups clearly defined and adequately assessed?</li> <li>Was the information used to define the exposure groups based on reasonable a priori data?</li> </ul>	<ul> <li>Low risk of bias: GDM was well defined, according to OGTT or relevant guideline and no measurement error is expected in its assessment.</li> <li>Moderate risk of bias: Exposure status is defined by diagnostic code (e.g. ICD) or by self-reported but measured by validated tool with satisfactory accuracy (≥90%) (e.g. validated questionnaire).</li> <li>Serious risk of bias: Exposure status is defined according to self-reported with unsatisfied accuracy (50-90%).</li> <li>Critical risk of bias: Exposure status is defined according to self-reported with poor accuracy (less than 50%).</li> <li>No information: No definition of exposure or no explanation of the source of information about</li> </ul>

Appendix S4. Description and decision criteria for each domain in ROBINS-I

		exposure status is reported.
Bias due to misclassification during follow-up	• Were there deviations from the exposure beyond what would be expected in usual practice?	Low risk of bias: Repeated measurements of the exposure status during follow-up are available. No or only slight changes in fat intake were observed and the changes were considered in the analysis. Moderate risk of bias: Repeated measurements of the exposure are not available, but high changes
and solo ap	• Were these deviations unbalanced between groups and likely to have affected the outcome?	<u>Moderate risk of blas</u> : Repeated measurements of the exposure are not available, but high changes are not expected during follow-up (compare notes) or repeated measurements of the exposure status during follow-up are available and some changes in lifestyle factors were observed. The analysis was appropriate to estimate the effect of changes in lifestyle factors, allowing for deviations that were likely to impact the outcome;
		<u>Serious or critical risk of bias:</u> Exposure status is measured during follow-up and high changes in lifestyle factors have been observed, and the analysis was not appropriate to estimate the effect of changes in lifestyle factors, allowing for deviations that were likely to impact the outcome.
		No information: No information on deviations from the exposure is reported.
Bias due to missing data	<ul> <li>Were there missing outcome data?</li> <li>Were participants excluded due to missing data on exposure status?</li> <li>Were participants excluded due to missing data on other variables</li> </ul>	Low risk of bias: Little loss-to-follow-up (<20%) and data on exposure and other variables were reasonably complete (<10% missing data) and was unlikely to introduce bias; <i>or</i> the analysis addressed missing data and is likely to have removed any risk of bias.
	needed for analysis?	<u>Moderate risk of bias:</u> There is a proportion of missing data in the original cohort or a high proportion of loss-to-follow-up; <i>and</i> the analysis is unlikely to have removed the risk of bias arising from the missing data (e.g., using logistic regression).
		Serious or critical risk of bias: High proportions (>50%) of missing data; <i>and</i> the analysis is unlikely to have removed the risk of bias arising from the missing data;
		<i>or</i> missing data were addressed inappropriately in the analysis; <i>or</i> the nature of the missing data means that the risk of bias cannot be removed through appropriate analysis.
		No information: No information is reported about missing data or the potential for data to be missing.
Bias due to measurement of the outcome	<ul> <li>Could the outcome measure have been influenced by knowledge of the exposure status?</li> <li>Were the methods of outcome assessment comparable across exposure groups?</li> </ul>	Low risk of bias: The methods of outcome assessment were comparable across exposure groups; <i>and</i> the outcome measure was unlikely to be influenced by knowledge of the exposure status of study participants; <i>and</i> any error in measuring the outcome is unrelated to exposure status (i.e., objective measures such as confirmed medical records, record linkage).
	<ul> <li>Was any systematic error in the measurement of the outcome related to exposure status?</li> </ul>	<u>Moderate risk of bias</u> : The methods of outcome assessment were comparable across exposure groups; <i>and</i> any error in measuring the outcome may be minimally related to exposure status <i>or</i> if the outcome measure was not reliable measured (i.e. confirmed records are not available for the whole study population).
		Serious or critical risk of bias: The methods of outcome assessment were not comparable across exposure groups; <i>or</i> the outcome measure was subjective (i.e., self-report of type 2 diabetes by study participants); <i>and</i> error in measuring the outcome was related to exposure status.

		No information: No information is reported about the methods of outcome assessment.
Bias due to selective reporting of the results	is the reported effect estimate micry to be selected from maniple	<ul> <li>Low risk of bias: There is a clear description of all analyses and the analyses are consistent and all reported results correspond to all intended outcomes, analyses and sub-cohorts.</li> <li>Moderate risk of bias: The analyses are clearly defined; <i>and</i> there is an indication of selection of the reported analysis from among multiple analyses; <i>and</i> there is an indication of selection of the cohort or subgroups for analysis and reporting on the basis of the results (e.g., estimates not shown for all analyses).</li> <li>Serious or critical risk of bias: There is a high risk of selective reporting from among multiple analyses; <i>or</i> the cohort or subgroup is selected from a larger study for analysis and appears to be reported based on the results.</li> <li>No information: There is too little information to make a judgment.</li> </ul>
Overall judgment	Low risk of bias	The study is judged to be at a low risk of bias for all domains.
	Moderate risk of bias	The study is judged to be at low or moderate risk of bias for all domains.
	Serious risk of bias	The study is judged to be at serious risk of bias in at least one domain, but not at critical risk in any domain.
