 Doi: 10.3389/fneur.2022.962227

Supplementary Material 1: Peripherin knockout mouse line genotyping and validation through cochlear immunofluorescence. A., Agarose gel electrophoresis of PCR amplicons delineates wildtype (+/++; 452 bp), heterozygous (+/-; 640 bp & 452 bp) and knockout (-/-; 640 bp) genotypes. B., The knockout genotype was confirmed by the absence of immunofluorescence labelling using post-natal day 8 (P8) *PrphKO* mouse cochlea. C. Image of type II spiral ganglion afferent neuron somata and their peripheral neurites which form the outer spiral bundles (OSB) in wild type P8 cochlea (anti-peripherin antibody batch-processed with the *PrphKO* tissue). SGN, spiral ganglion neurons; OSL, osseous spiral lamina; OHC, outer hair cells; IHC, inner hair cells. B and C are 3D projections of confocal optical sections acquired from 50 μm cryosections immunolabelled with the anti-peripherin antibody and alexa488 fluorescent secondary antibody.

Cederholm *et al.* Frontiers in Neurology - Neuro-Otology. **Noise-induced hearing loss vulnerability in type III intermediate filament peripherin gene knockout mice**
Doi: 10.3389/fneur.2022.962227

Supplementary Material 2: Video 1. Projected confocal image stack of CtBP2 immunofluorescence (green) highlights the regular synaptic ribbon structure at the base of the three rows of outer hair cells, with one or two discrete puncta beneath the nucleus, compared with the dense synaptic ribbon complex associated with the basolateral membrane of each inner hair cell (WT cochlear organ of Corti). Type II spiral ganglion afferents (type II SGN) form the outer spiral bundle beneath the Deiters' cells (NF 200 immunofluorescence – red) and project apically to the OHCs (upper left). This neural labelling includes the dense inner spiral plexus of the type I spiral ganglion neurite innervation (type I SGN) of each inner hair cell (IHC) – juxtaposed to the dense ribbon complex (upper right). The NF 200 immunofluorescence also extends to the dense matrix of medial olivocochlear (MOC) efferent fibres crossing the tunnel of Corti to innervate the outer hair cells. This projection extends the visualisation of Figure 1C. **Filename: Cederholm et al. SIvideo1.wmv**

Doi: 10.3389/fneur.2022.962227

Supplementary Material 3: Figure 2 supplement 1. Disruption of outer spiral bundle structure (OSB; type II spiral ganglion neuron dendrites (type II SGN)) in mid-cochlear region of the Prph knockout (KO) resolved using β -III tubulin immunofluorescence. Confocal transparent-mode 3D reconstructed images of batch-processed WT and PrphKO cryosections with the basilar membrane surface oriented uppermost to optimally delineate the OSB. **A**, In the WT cochlea, the outer spiral fibres (type II SGN) within the OSB (arrowhead) run vertically below the three rows of outer hair cells (OHCs). The medial olivocochlear (MOC) efferent fibers project horizontally from the inner spiral plexus (ISP) region, to the OHC region, where they branch to form large synaptic boutons (*) at the base of multiple OHCs. **B**, In the PrphKO image, the OSB are not evident (open arrowhead), while equivalent MOC efferent fiber projections extend to the OHCs and form synaptic boutons (*). IHC, inner hair cells.

Doi: 10.3389/fneur.2022.962227

Supplementary Material 4: Video 2. β -III tubulin immunofluorescence of innervation of the organ of Corti in the apical region of the wildtype mouse. Type II spiral ganglion afferents (type II SGN) form outer spiral bundles of small diameter unmyelinated neurites that run beneath the three rows of outer hair cells. Whole-mount maximum intensity projection of a confocal image stack (48 μ m) imaged from the basilar membrane surface. The inner spiral plexus of type I spiral ganglion neurites (type I SGN) innervate the single row of inner hair cells. The medial olivocochlear (MOC) efferent fibres are shown crossing the tunnel of Corti to innervate the outer hair cells. This projection extends the visualization of Figure 3A. **Filename: Cederholm et al. SIvideo2.wmv**

Doi: 10.3389/fneur.2022.962227

Supplementary Material 5: Video 3. β -III tubulin immunofluorescence of innervation of the organ of Corti in the apical region of the PrphKO mouse. Whole-mount maximum intensity projection of a confocal image stack ($48 \mu\text{m}$) imaged from the basilar membrane surface from tissue batch-processed with the WT reference (SI Video 2). Note the reduced representation of Type II spiral ganglion afferents (type II SGN) in outer spiral bundles. Inner spiral plexus of type I spiral ganglion neurites (type I SGN) innervate the single row of inner hair cells. The medial olivocochlear (MOC) efferent fibres cross the tunnel of Corti to innervate the outer hair cells. This projection extends the visualisation of Figure 3B.

Doi: 10.3389/fneur.2022.962227

Supplementary Material 6: Figure 4 supplement 1. NF200 immunofluorescence labelling (maximum intensity projections) of batch-processed wholemounts from the apical region of wildtype (WT) and PrphKO organ of Corti. Note the lack of outer spiral fibres within the outer spiral bundle (OSB; type II SGN afferent fibres) in the KO tissue, while medial olivocochlear (MOC) efferent projections to the outer hair cell region from the inner spiral plexus region (ISP) are equivalent. To optimally resolve the OSB fibre tracts, the tissue was imaged with the basilar membrane surface closest to the microscope objective, as the OSB lies beneath the MOC fibres.

Doi: 10.3389/fneur.2022.962227

Supplementary Material 7: Figure 6 supplement 1. Evidence of disruption of the type II SGN afferent synapses with the outer hair cells (OHC) in the PrphKO cochlea. CtBP2/RIBEYE immunofluorescence (green puncta) localizes pre-synaptic ribbon complexes at the base of OHCs and inner hair cells (IHC). While this labelling is consistent between WT and KO at the IHC synapses (inner spiral plexus region, ISP), there is pronounced apical migration of many of the synaptic ribbons away from the synaptic pole of the KO OHCs (compare filled arrows for WT and open arrows for KO). In contrast, the medial olivocochlear efferent synaptic boutons (VACHT immunofluorescence, red) are retained in the mid and medial aspects of the synaptic pole of the OHCs in the WT and KO cochlea. Nuclei labelled with DAPI. 50 μ m cryosections.
