

Supplemental Figure 3: No statistical differences in T cell responses due to gender. The medium of max (MoM, see methods) for the results obtained by (A) the 4-day IFN γ ELISpot and (B) Lymphocyte Stimulation Test (LST) from female (F) and male (M) patients per dose cohort (indicated by the number) is depicted. As the female-male ratio in cohort 1 and 4 were unbalanced, only for dose cohorts 2 and 3 a statistical analysis (Mann Whitney test) could be performed, which resulted in no significant differences.
