

**Supplementary Fig. S1** Allele frequency distribution of all 20,137 single nucleotide polymorphisms (SNPs) before (a) and after (b) filtering. Filtering was performed retaining SNPs with less than 5% missing values, allele frequencies between 0.05 and 0.95 in at least 10 accessions and mean allele frequencies across all accessions between 0.05 and 0.95 ( $0.05 < \text{MAF} < 0.95$ )

**Supplementary Fig. S2** Single nucleotide polymorphism (SNP) density on the seven *Trifolium pratense* chromosomes. The y-axis represented the interval distance in Mbp. The window size to calculate SNP density was 250kb

**Supplementary Fig. S3** Linkage disequilibrium (LD) decay against the genetic distance for pairs of SNPs across all seven chromosomes of the red clover genome. LD estimates are reported as squared correlations of allele frequencies ( $r^2$ ). The red solid line depicts the smoothed fitted line calculated using the LOESS method. Vertical dotted line is drawn at 10,000 bp

**a** LG1\_6601280

$R^2 = 0.168$   
Coefficient ( $\beta$ ) = - 89.4

LG7\_6328288

$R^2 = 0.09$   
Coefficient ( $\beta$ ) = - 56.3

LG6\_16830298

$R^2 = 0.067$   
Coefficient ( $\beta$ ) = 25.1

Scaf595\_126629

$R^2 = 0.063$   
Coefficient ( $\beta$ ) = - 20.9

LG1\_2684496

$R^2 = 0.044$   
Coefficient ( $\beta$ ) = - 30.0

Scaf323\_195382

$R^2 = 0.04$   
Coefficient ( $\beta$ ) = 19.4

Scaf215\_144740

$R^2 = 0.036$   
Coefficient ( $\beta$ ) = - 20.0

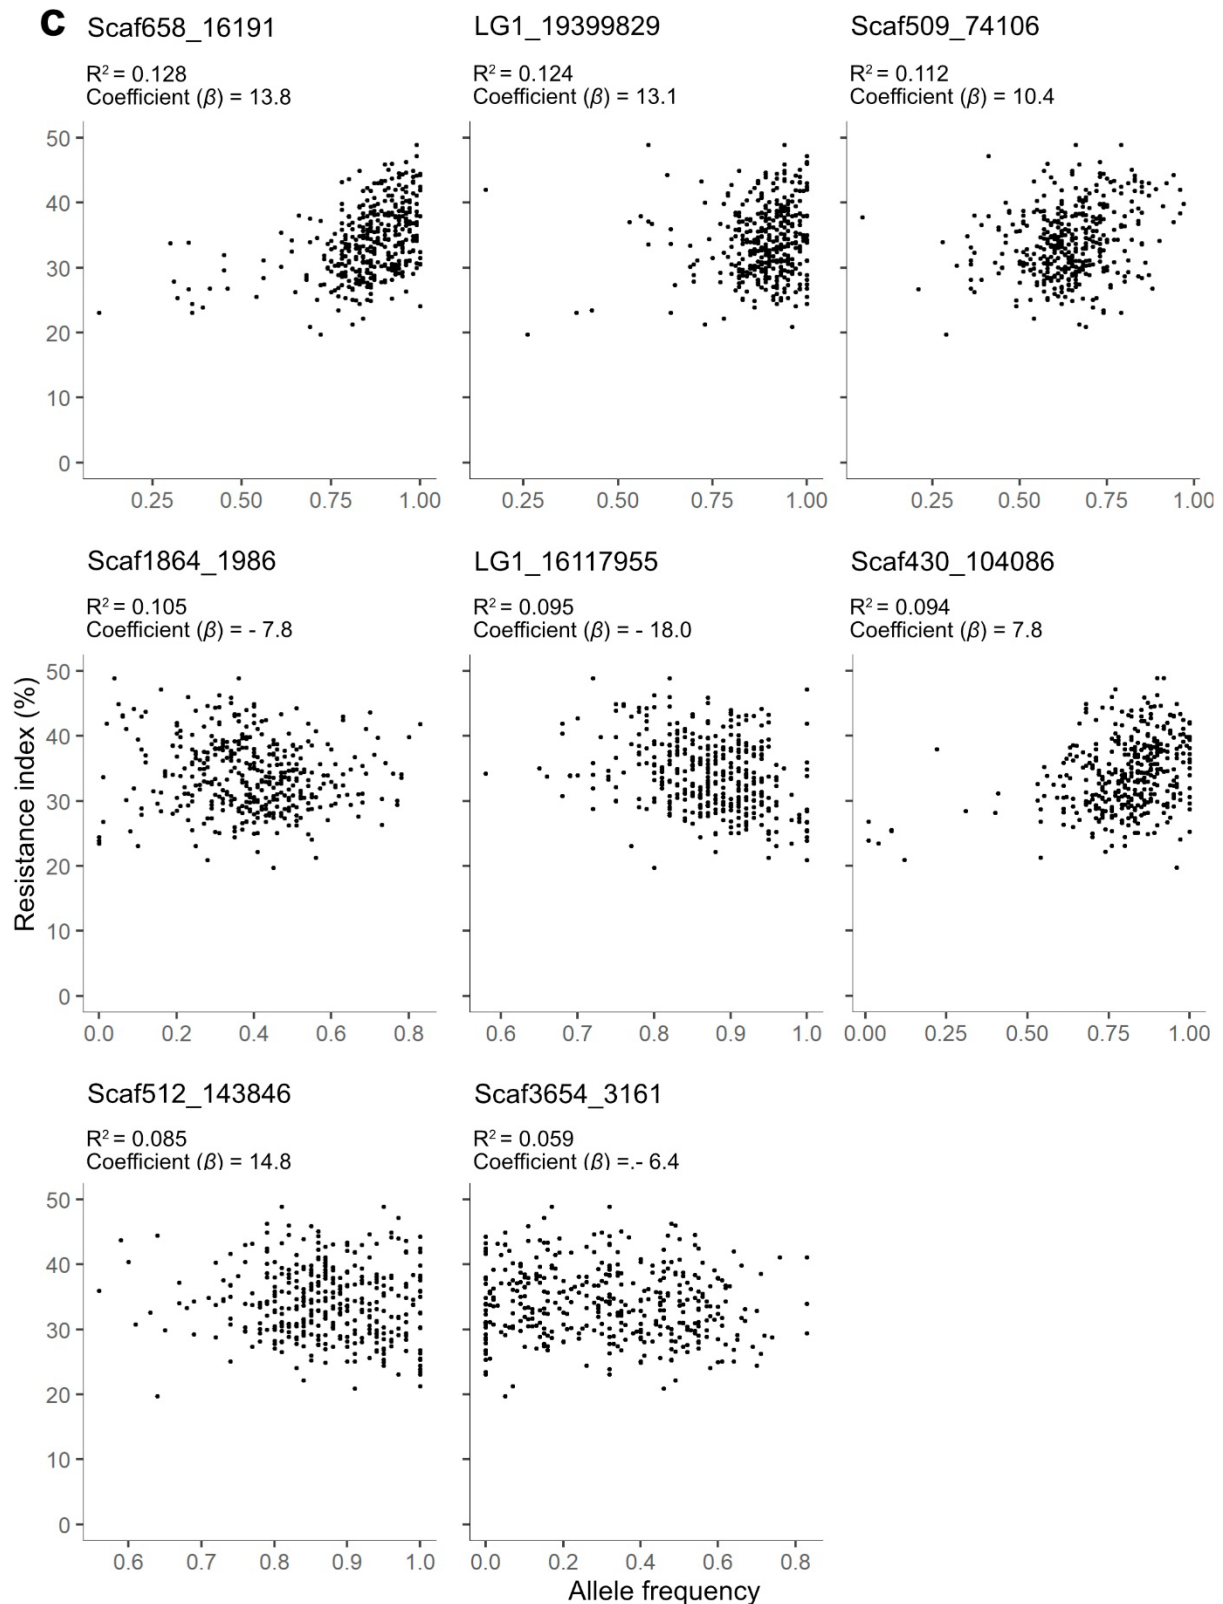

Scaf8613\_1314

$R^2 = 0.035$   
Coefficient ( $\beta$ ) = - 36.8

Allele frequency

**Supplementary Fig. S4** Scatter plots of the BLUEs corrected mean phenotypic observations and allele frequencies separate for each significantly associated SNP. Horizontal axes show the allele frequencies. Vertical axes depict the survival rate (%) for single-spore inoculation (a), back-transformed cumulative survival rate (%) for mixed-spore inoculation (b), and resistance index for

clover rot (c). The coefficient of determination  $R^2$  is calculated by comparing a linear model taking SNPs as fixed effects and the kinship matrix as random effect to the  $R^2$  of the same model without integrating the SNPs. Coefficient ( $\beta$ ) is the slope of a linear model taking phenotypic observations as response variable, significantly associated SNPs as fixed effects and the kinship matrix as random effect
