Supplementary Figure 1: The comparison of microbial diversity between Parkinson's
disease patients and healthy controls. (a) Alpha diversity indexes. (b) Principal coordinates
analysis (PCoA) based on Bray-Curtis distance. H (Healthy control). P (Parkinson's disease
patient).

27

Supplementary Figure 2: Co-occurrence networks. Co-occurrence networks were calculated based on Spearman correlations at the operational taxonomic unit (OTU) level. Only strong (r >0.7) and significant (p < 0.05) correlations are shown in the figure. (a) Healthy controls. (b) Patients with Parkinson's disease (PD). The difference between this figure and Fig. 5 is that the nodes with few connections (< 5) were not removed and the nodes in this figure were colored by genus. On the right of the graph, only the unclassified and five genera with the highest number of nodes were labeled.

37

Supplementary Figure 3: Differences in microorganisms and genes between healthy controls and patients with Parkinson's disease (PD). (a) Genera with significant differences in relative abundance. (b) Genes (related to inflammation) with significant differences in transcripts per million (TPM) abundance. SCFAs: short-chain fatty acids.

Supplementary Figure 4: The maximum-likelihood phylogenetic tree. The tree was based on the 120 bacterial concatenated ribosomal proteins, colored by phyla. Bootstrap values were calculated based on 1000 replicates, and the value higher than 80% were marked in yellow. The size of the blue (pro-inflammatory gene) and red (anti-inflammatory gene) circle indicates the number of inflammation-related genes. Blue (significant increase in PD) and red (significant decrease in PD) stars indicate significant differences in the relative abundance of metagenomeassembled genomes (MAGs). Parkinson's disease (PD).
