

Cross-scale regulation of seasonal microclimate by vegetation and snow in the Arctic tundra

von Oppen J. et al. 2022 *Global Change Biology*

Supplementary note

Stratified random placement of sample plots

For placement of scattered plots, we first computed one random candidate location for each of the six classes (three vegetation x two moisture classes; Table S1) within each elevation band on each mountainside. Depending on availability within a class, we additionally computed up to five alternative random locations for each of these plots, resulting in 60 candidate and ~300 alternative locations. Furthermore, we placed an additional 30 plots located in clustered “core-areas” on the eastern mountain slope to include high environmental variation within small spatial scales. Candidates for the core areas were selected from the list of all candidate sampling locations for the scattered plots (incl. alternatives) by choosing locations for which all six sampling classes of the landscape stratification were present within a 60 m radius around the location. Thereafter, we removed these core area locations from the lists of original locations - while maintaining their random order - and selected the first core area candidate as the prime candidate and the rest as alternatives. We then applied the random stratified sampling again, this time to generate an additional five locations within the 60 m radius around each potential core area centre by sampling the remaining five classes not covered by the centre location itself.

In the field, we established the sample plots based on the candidate locations where possible, working through the list of alternatives where lack of access, human disturbance (e.g. a path) or placement of the logger was not possible (see below for more details). We used handheld GPS devices (GARMIN eTrex 30, Garmin Ltd., Schaffhausen, Switzerland) to find plot locations with the predefined coordinates. Once the GPS reported arrival at the location, we placed a metal peg to mark the centre of the plot. In cases where placement of the peg and/or both loggers was not possible (e.g. due to shallow soil, solid rock, or standing water), we repeated the attempt

50 cm north, east, south and west of the original location. If necessary, further attempts were taken at 100, 150, and 200 cm in all cardinal directions. If placement was still not possible, we skipped the location and repeated the procedure at the next alternative location. In two cases, this resulted in placement of sample plots on the eastern instead of the western mountain slope, but in the same elevation band.

Hindsight assessment of vegetation cover across intended productivity classes confirmed that this part of the stratification was successful (Figure S10a). In contrast, comparison of local growing-season mean soil moisture across NDWI classes revealed that our study design did not systematically capture differences in water availability (Figure S10b). However, this mismatch could partly be due to between-year moisture variation, as the growing season of 2018 saw much more precipitation than the rather dry summer of 2019.

Supplementary figures

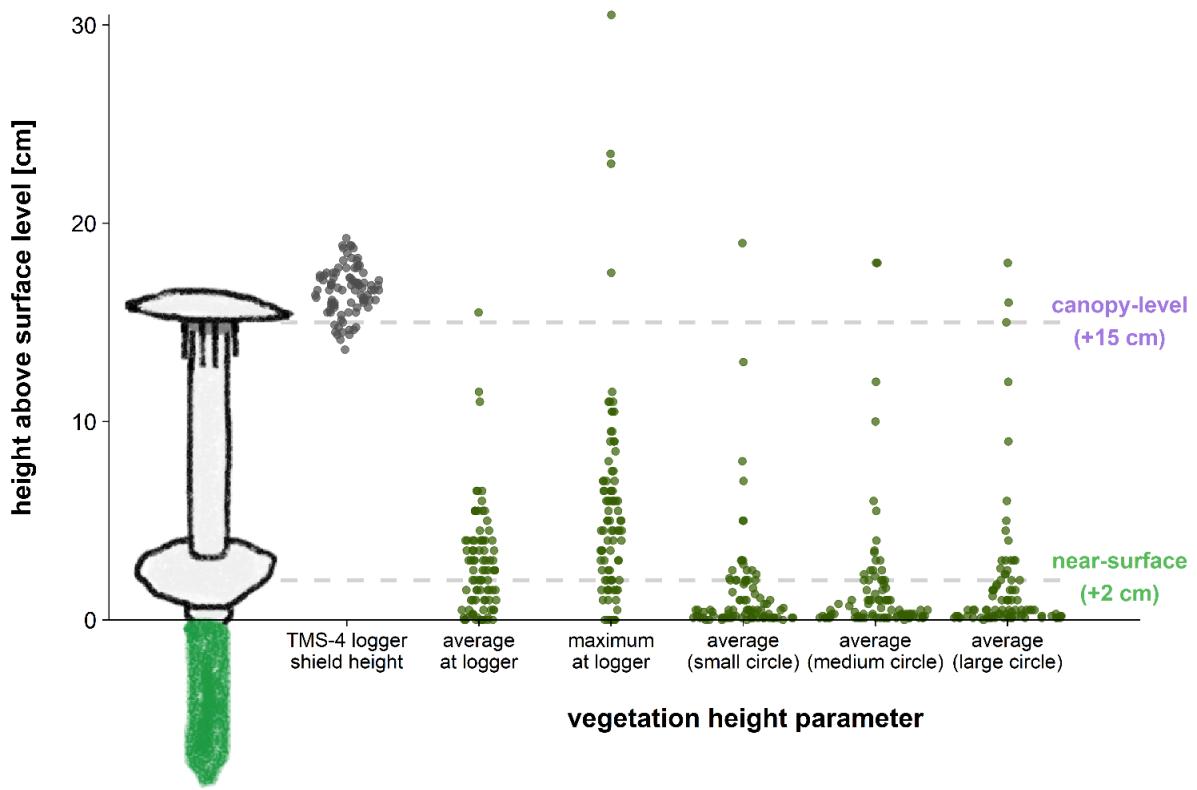

Figure S1:

The top (= air) sensor of the microclimate logger reached above the vegetation in most plots. Dots show the distributions of height measurements for the top shield of the TOMST TMS-4 logger and for vegetation at the logger as well as in each sampling circle (see Figure 1 in the main text). Dashed horizontal lines indicate position of the above-ground temperature sensors on the logger for reference.

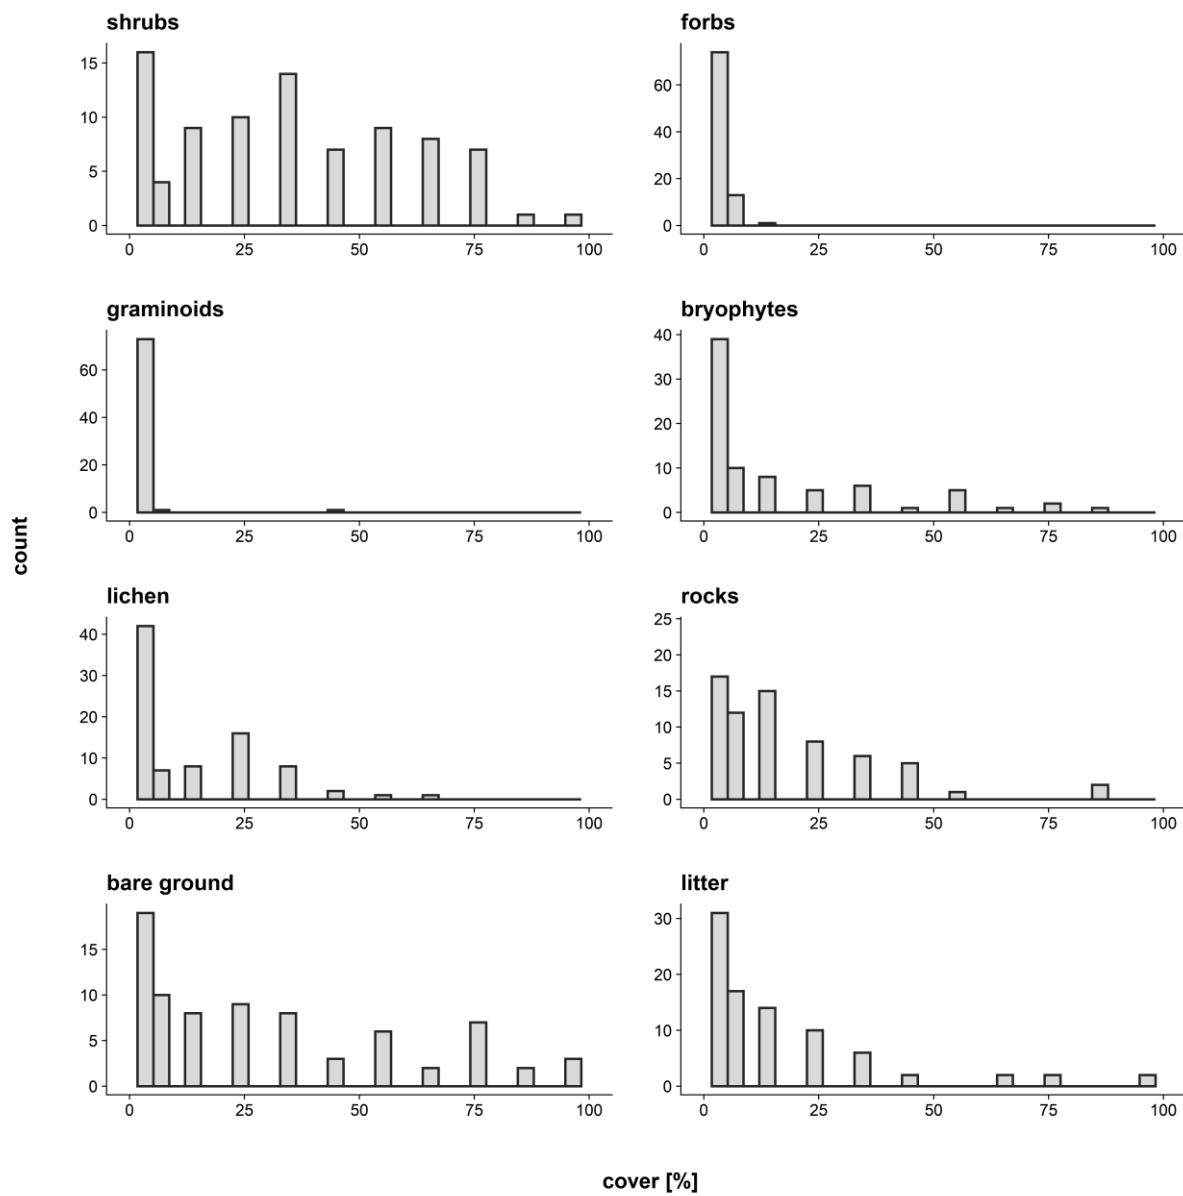

Figure S2:

Histograms of cover values for different categories in sample plots. Scarce forb and graminoid cover were excluded from analysis.

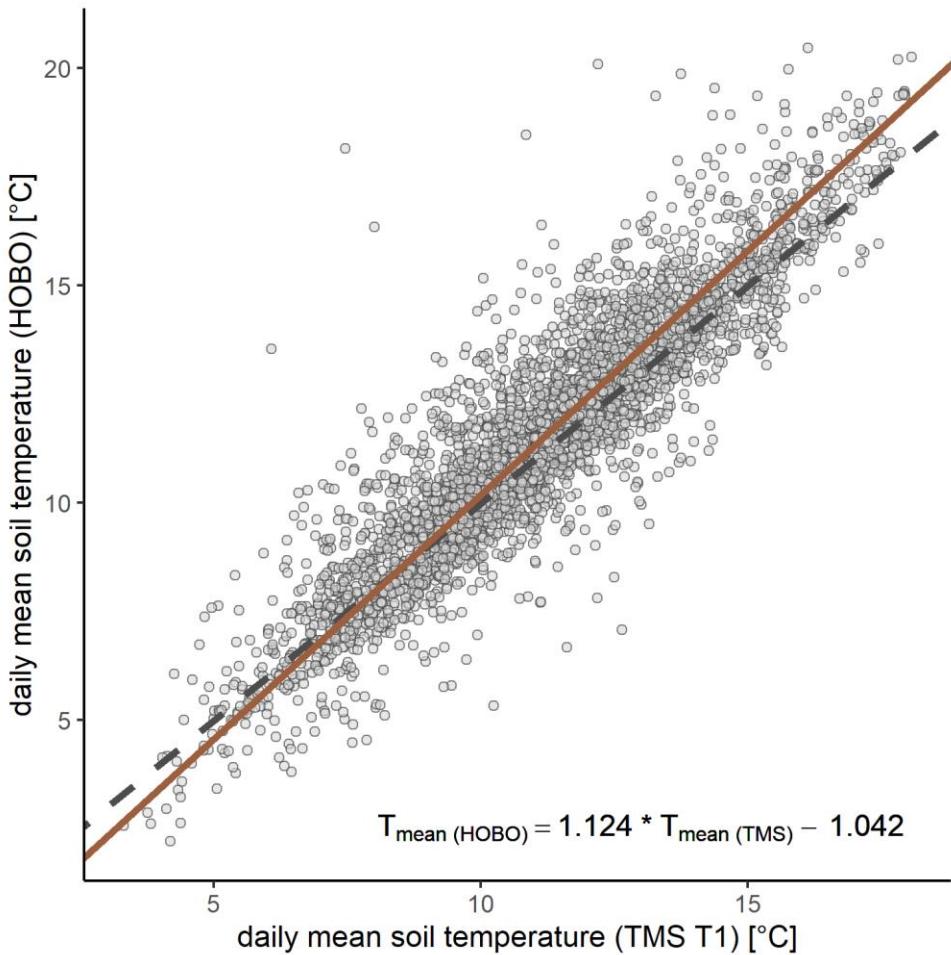

Figure S3:

Growing-season soil temperature measurements were well aligned between TMS and HOBO sensors.

Points represent measurement pairs of daily mean temperature. The brown line shows the fitted linear relationship (coefficients shown in equation), and the grey dashed line presents the 1:1 relationship for comparison.

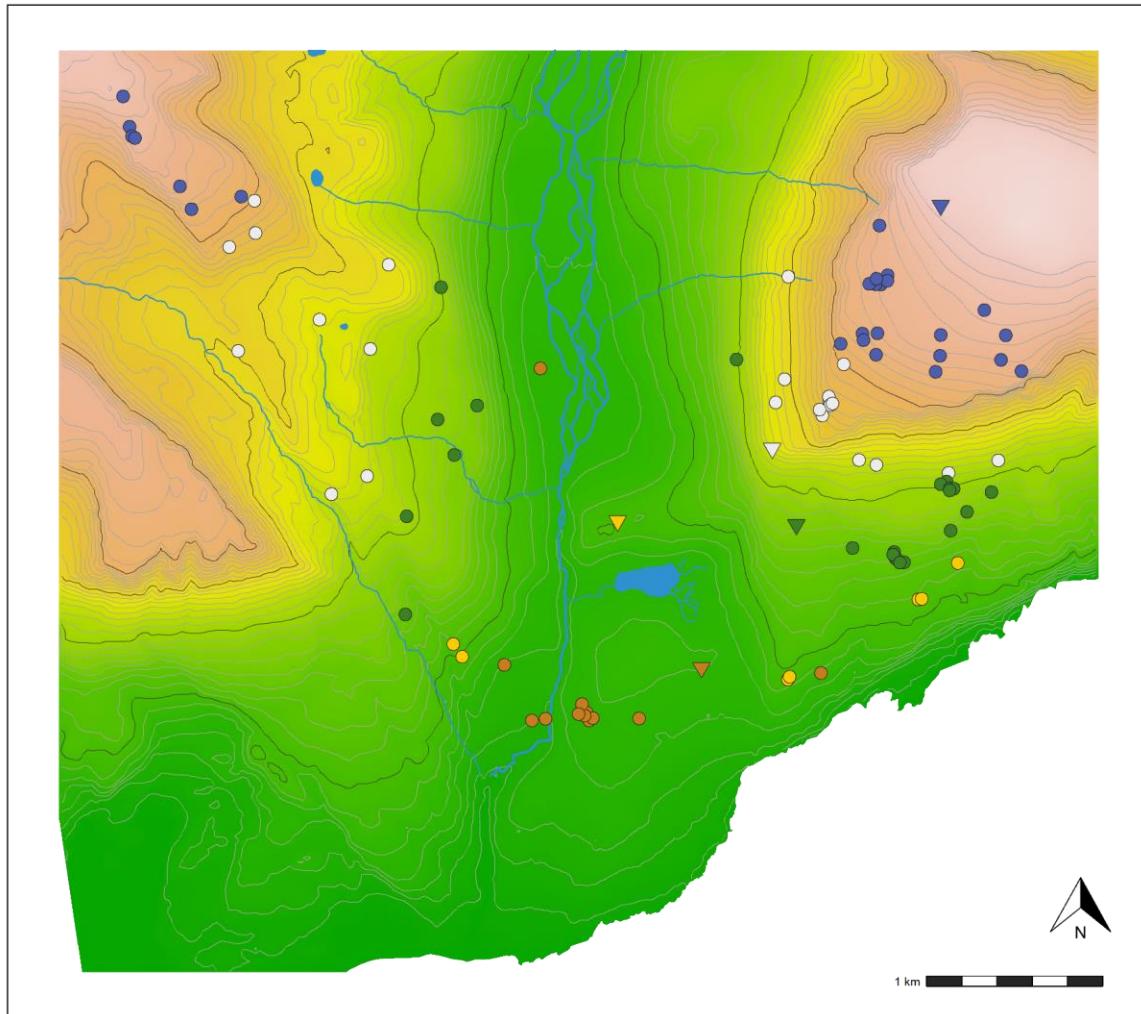

Figure S4:

Weather station with the smallest elevation difference to each sample plot, of which the free-air temperature time series was used to calculate temperature differences. See also Figure 1 in the main text for a description of plot placement.

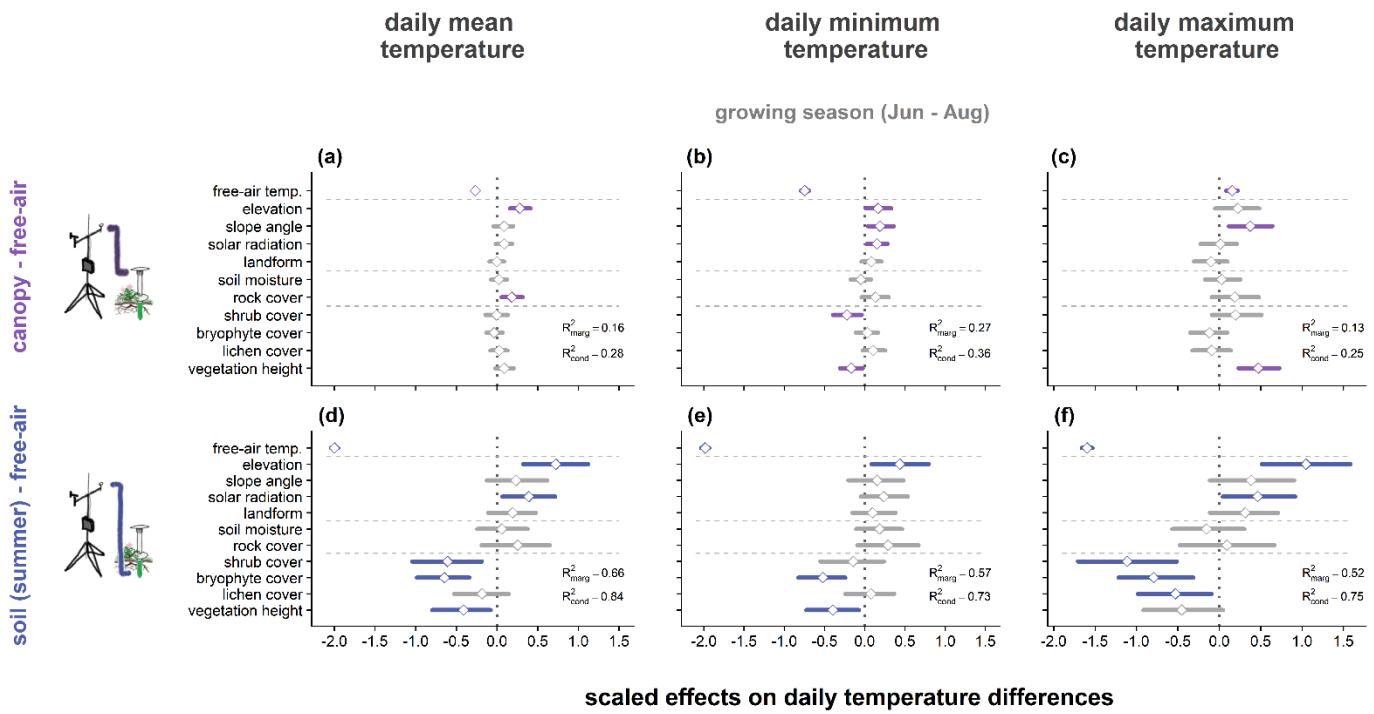

Figure S5:

Local factors weakly influenced differences between free-air weather stations and TMS canopy sensors (**a-c**), resulting in relationships of soil vs. free-air ΔT with environmental variables largely consistent with those of soil vs. canopy-layer ΔT (**d-f**; compare Figure 4a-c in main text). Exceptions include significant positive relationships of soil vs. free-air ΔT_{mean} with elevation and solar radiation, as well as a non-significant relationship of soil vs. free-air ΔT_{max} with more exposed landforms and vegetation height. These differences might be partly attributable to elevational and topographical mismatches between plot and weather station locations (see Figure S4).

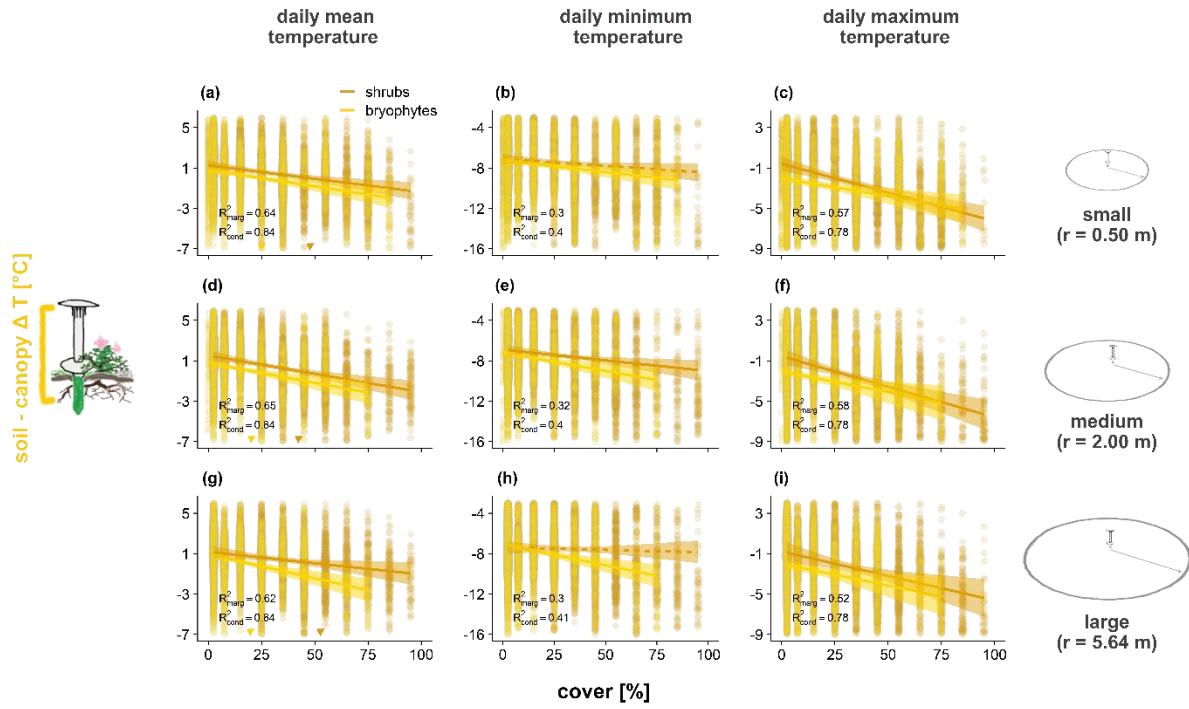

Figure S6:

Growing season temperature differences between canopy level and soil shift from warmer to cooler soils with higher shrub and bryophyte cover. The relationships were consistent across plot sizes, as vegetation cover measures were highly correlated across plot sizes (Table S7). This figure is identical to Figure 5 in the main text, but also shows the data points for daily temperature variables for each plot.

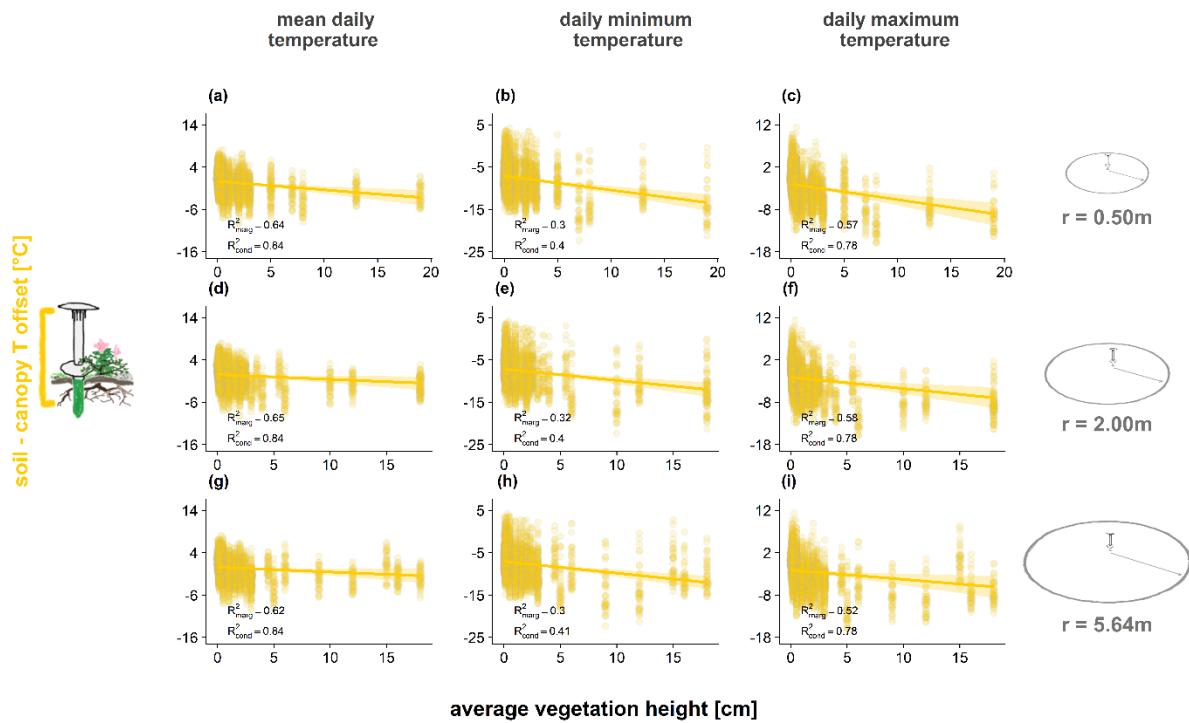

Figure S7:

Growing season temperature differences between canopy level and soil increase with taller vegetation.

As height values were highly correlated (Table S7), this relationship was consistent across plot sizes.

The panels show predicted relationships (solid green lines with light-green 95% credible intervals) between the average vegetation height within a plot and the observed difference between soil and canopy-level temperatures for the daily mean, minimum and maximum temperatures over the 2019 growing season. We measured the average vegetation height for three different sizes of circles around the centre of the plots; these circles had radii of **(a-c)** 0.5 m, **(d-f)** 2 m and **(g-i)** 5.64 m. Note that loggers and circle sizes on the right are not to scale.

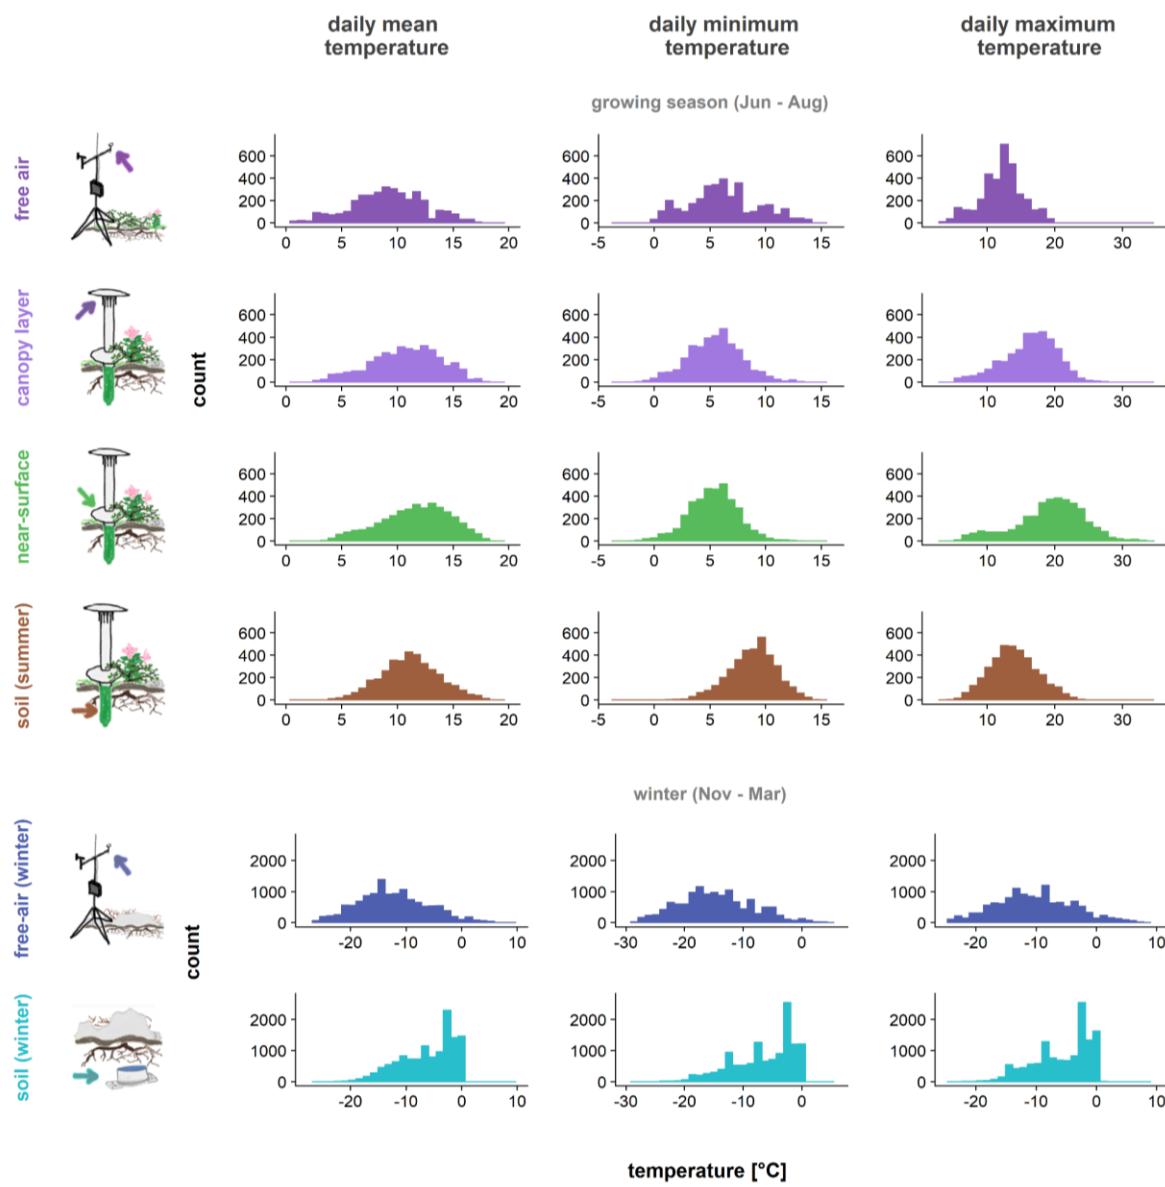

Figure S8:

Histograms of seasonal mean temperatures across the vegetation profile, per plot or weather station. Narrow distribution in weather station values is due to the low number of stations present and only a subset of these being highly correlated with air or soil temperatures in the plots (Figure S4).

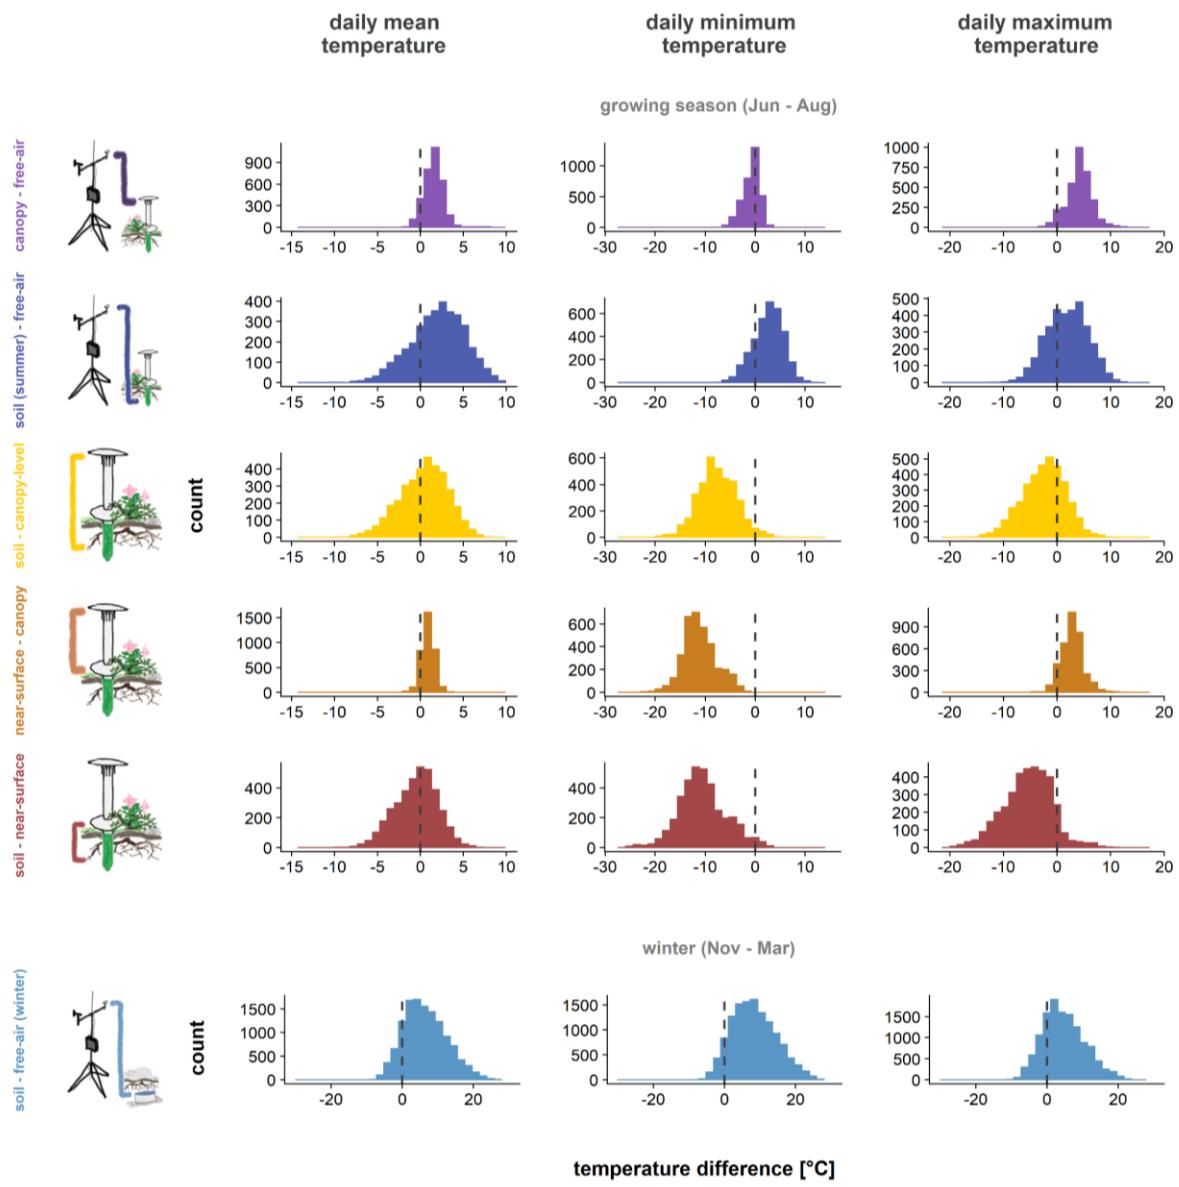

Figure S9:

Histograms of differences between daily mean, minimum and maximum temperatures in different layers of the vegetation profile. Negative values point to colder lower layers compared to higher elevated ones, while positive values indicate higher temperatures in lower layers. Note that vertical axis ranges vary between panels.

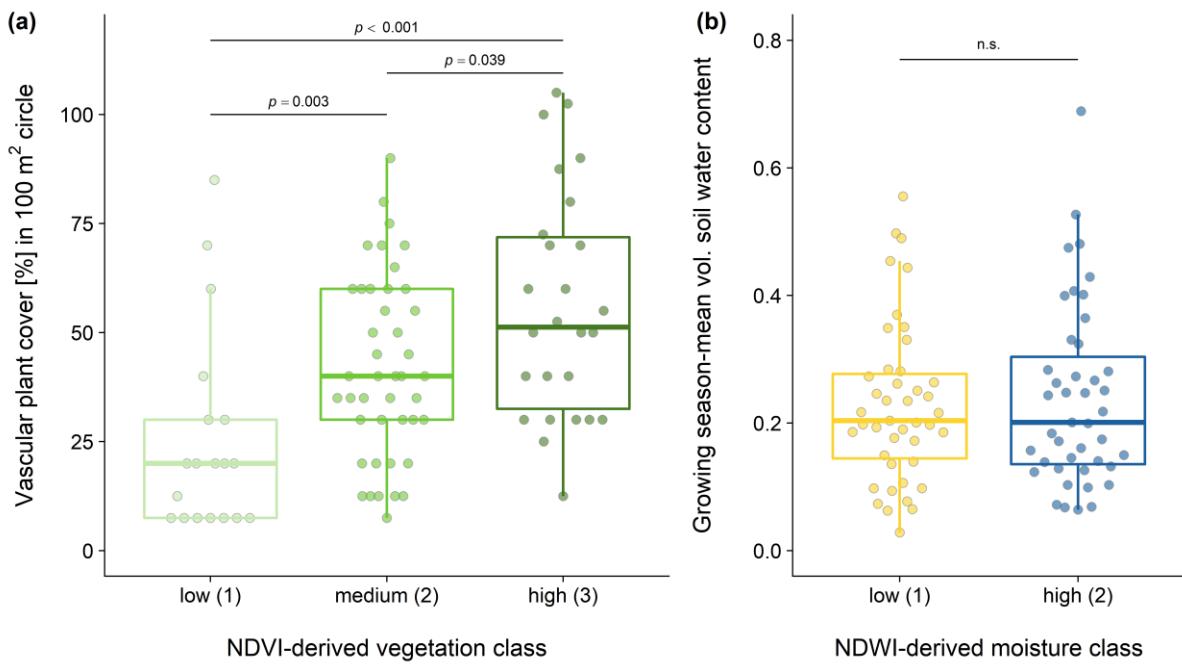

Figure S10:

The stratified-random sampling design succeeded to capture different vegetation cover, but not moisture conditions. **(a)** Cover values represent summed cover of shrubs, graminoids and forbs and could exceed 100 % in case of overlapping vegetation layers. **(b)** Soil moisture values were scaled across the range of daily mean values. P values were obtained from a Kruskal-Wallis test ($\chi^2 = 17.78$, df = 2) with post-hoc correction.

Supplementary tables

Table S1: Threshold values for the definition of vegetation and moisture classes. For vegetation classes, values are based on Normalised Difference Vegetation Index (NDVI), for moisture classes, values are based on Normalised Difference Wetness Index (NDWI). The thresholds were determined based on the distribution of values across the study area using k-means clustering.

Vegetation	NDVI	Moisture	NDWI
Low	> -0.21477	Low	> -0.38214
			< -0.02306
	< 0.17910	High	> -0.02306
			< 0.49108

Table S4: Predictor variables included in the different models of temperature responses across both seasons.

Groups include temperature / temperature difference responses across all vegetation layers. Cover variables were included at their respective sampling resolution (plot radius 0.50, 2.00 or 5.64 m) into cross-scale models of growing-season temperature differences. See Table S5 for other predictors removed to avoid collinearity.

Temperature response group	Model formula
Growing-season daily [mean/min/max] temperature	temperature ~ daily free-air temperature + elevation + slope angle + solar radiation + landform + soil moisture + rock cover + shrub cover + bryophyte cover + lichen cover + average vegetation height + (1 plot ID)
Growing-season daily difference in [mean/min/max] temperature	temperature difference ~ daily free-air temperature + elevation + slope angle + solar radiation + landform + soil moisture + rock cover + shrub cover + bryophyte cover + lichen cover + average vegetation height + (1 plot ID)
Winter daily [mean/min/max] temperature	temperature ~ daily free-air temperature + elevation + slope angle + solar radiation + landform + snow cover duration + rock cover + shrub cover + average vegetation height + (1 plot ID)
Winter daily difference in [mean/min/max] temperature	temperature difference ~ daily free-air temperature + elevation + slope angle + solar radiation + landform + snow cover duration + rock cover + shrub cover + average vegetation height + (1 plot ID)

Table S5: Pearson correlation coefficients between all potential predictor variables for the small circles (radius 0.5 m). Either growing-season solar radiation, soil moisture, bryophyte and lichen cover (*, growing season) or snow cover duration and winter solar radiation (#, winter) were included as season-specific predictors (see also Table S4 for predictors included into each model). Shaded variables were removed prior to analyses to avoid collinearity with remaining variables. For clarity, only correlations with $|r| > 0.3$ are shown.

Table S7: Predicted threshold cover percentages for switch from warmer to colder soils compared to canopy-level mean temperatures during the growing season. See also Figure 4 a,d,g for graphed relationships.

sample plot size (radius)	cover variable	threshold cover %
small (0.50m)	shrubs	50.99
small (0.50m)	bryophytes	29.06
medium (2.00m)	shrubs	44.87
medium (2.00m)	bryophytes	23.21
large (5.64m)	shrubs	56.44
large (5.64m)	bryophytes	22.50

Table S8: Pearson correlation coefficients for shrub and bryophyte cover and average vegetation height across sample plot sizes.

variable	bryophyte cover (r = 0.5 m)	bryophyte cover (r = 2.0 m)	bryophyte cover (r = 5.64 m)	shrub cover (r = 0.5 m)	shrub cover (r = 2.0 m)	shrub cover (r = 5.64 m)	average vegetation height (r = 0.5 m)	average vegetation height (r = 2.0 m)	average vegetation height (r = 5.64 m)
