

1 **Supplementary Materials**

2 **Materials and Methods**

3 *1. Biological characterization*

4 *1.1 Virus titration*

5 Virus titers of the two strains were measured, expressed as a half tissue culture infection
6 dose (TCID₅₀). In a nutshell, a 10-fold gradient dilution of virus suspension was
7 inoculated into Vero cells cultured in 96-well plates with a total of 11 gradients diluted,
8 and each gradient had 8 replicates. The cytopathic effect (CPE) was observed after 72h
9 incubation at 37°C, and TCID₅₀ was calculated using Reed-Muench method (1).

11 *1.2. One-step growth curve determination*

12 The one-step growth curves of two GETV isolates were measured on Vero cells and
13 PK15 cells, respectively. The multiplicity of infection (MOI) was calculated according
14 to the measured TCID₅₀. Vero cells and PK15 cells were cultured in 24-well plate and
15 inoculated with MOI=0.001 and MOI=0.1, respectively. Cell cultures were collected at
16 12h, 24h, 36h, 48h, 60h, and 72h post infection (hpi) and their corresponding CPE was
17 observed, TCID₅₀ of these cultures' supernatants were measured by Reed-Muench
18 method in turn, with three replicates for each hpi.

20 *1.3. Immunofluorescence assay (IFA)*

21 IFA was performed on monolayer cultured cells in 96-well plates, and GETV isolates
22 were inoculated on Vero cells and PK15 cells according to MOI=0.001 and MOI=0.1,
23 respectively. After incubating for 1h at 37°C, remove the inoculum and replace with
24 fresh DMEM containing 2% FBS to maintain the culture for 24h. The cells were then
25 fixed with 4% paraformaldehyde, incubated at room temperature for 30 min and washed
26 with PBS for 3 times. Next, the cells were sealed with 5% skim milk, incubated at 37°C
27 for 1h and washed three times with PBS. The cells reacted with 1:500 diluted GETV-
28 E2 poly-antibody (prepared in our laboratory) and were incubated at 37°C for 1h, then
29 inoculated with FITC-conjugated secondary antibody at 37°C for 1h. Finally, add 4',6-

30 diamidino-2-phenylindole (DAPI, Solarbio, China) to stain the nucleus, the cells were
31 incubated for 10 min at room temperature and observed under a differential
32 fluorescence microscope (Nikon, Tokyo, Japan).

33

34 *1.4. Mouse infection test of GETV*

35 In the pathogenicity experiments on mouse models of GETV-GX strain, 3-day-old ICR
36 suckling mice were inoculated intracranially with 25 μ l of $10^{6.5}$ TCID₅₀/0.1 ml GETV
37 viral solution or with DMEM. Weight and survival status were observed and recorded
38 every 24 hours until all GETV-infected suckling mice died. Mice injected with DMEM
39 (Mock group) were euthanized. Survival analysis was performed in GraphPad software.
40 The significance between survival mice infected with GETV and DMEM was estimated
41 using a log rank test; ***P < 0.001.

42

43 *2. Investigating the impact of environmental factors on the dispersal location and* 44 *dispersal velocity of GETV lineages*

45 For investigating the impact of environmental factors on the dispersal location of GETV
46 lineages, we used an analytical procedure where mean environmental values are
47 extracted and compared at node positions in inferred (E_{inferred}) and simulated ($E_{\text{simulated}}$)
48 trees (2). Simulated trees were obtained by re-simulating a relaxed random walk
49 diffusion process along the same trees sampled from the posterior distribution under
50 two constraints: the location inferred for the root of the trees is unchanged, and the
51 simulated tree node positions cannot fall in non-accessible areas (such as sea areas).
52 $E_{\text{simulated}}$ values thus correspond to the distribution of mean environmental values
53 explored by phylogenetic nodes under a null dispersal model, i.e. a dispersal scenario
54 that is not impacted by underlying environmental factors. For each tested environmental
55 factor, the E_{inferred} distribution was compared to the $E_{\text{simulated}}$ one to assess if GETV
56 lineages tended to preferentially circulate within or avoid specific environmental
57 conditions, a comparison formalized by the approximation of a Bayes factor support
58 (2).

59

60 For investigating the impact of environmental factors on the dispersal velocity of GETV
61 lineages, we employed an analytical procedure where dispersal durations associated
62 with phylogenetic branches are compared to environmental distances computed on each
63 environmental grid (or “raster”). These environmental distances were computed with
64 two path models: the least-cost path model (3) and the path model implemented in the
65 program Circuitscape (4), the latter using circuit theory to accommodate uncertainty in
66 the route taken. The algorithm implemented in Circuitscape treats a given
67 environmental raster as a conductance (facilitating movement) or as a resistance
68 (impeding movement) factor. In the context of the present study, we tested the potential
69 impact of each environmental factor acting once as a conductance and once as a
70 resistance factor. Moreover, for each environmental factor, we generated several
71 distinct rasters by transforming the original raster cell values with the following formula:
72 $v_t = 1 + k(v_o/v_{max})$, where v_t and v_o are the transformed and original cell values, and v_{max}
73 the maximum cell value recorded in the raster. The rescaling parameter k here allows
74 the definition and testing of different strengths of raster cell conductance or resistance,
75 relative to the conductance/resistance of a cell with a minimum value set to “1”, which
76 corresponds to the “null” raster (see below). For each of the three environmental factors,
77 we tested three different values for k : $k = 10, 100$ and 1000 . Correlations between
78 phylogenetic branch durations and environmental distances are estimated through the
79 computation of the statistic Q , which is the difference between the coefficient of
80 determination obtained when branch durations are regressed against environmental
81 distances computed on the environmental raster and the coefficient of determination
82 obtained when branch durations are regressed against environmental distances
83 computed on a “null” raster (i.e. a uniform raster with a value of “1” assigned to all
84 cells). We estimated a Q statistic for each environmental factor (treated a conductance
85 or a resistance factor) and each of the 1,000 trees sampled from the posterior
86 distribution. An environmental factor was only considered as potentially explanatory if
87 both its distribution of regression coefficients and its associated distribution of Q values

88 were positive (5), i.e. with at least 90% of positive values. In this case, the statistical
89 support associated with the resulting Q distribution was compared with the
90 corresponding null of distribution of Q values obtained when computing environmental
91 distances for phylogenetic branches of trees simulated under the null dispersal model
92 introduced above. Similar to the investigation of the procedure used to explore the
93 impact of environmental factors on the dispersal locations of lineages, the comparisons
94 between inferred and simulated distributions of Q values were formalized by
95 approximating Bayes factor support (6).

96

97 **Result**

98 *Sequence similarity*

99 A total of 78 GETV positive sample were detected in 16 provinces in China, from 2017
100 until now. Two pet canines, and one bovine were found infected GETV. There was no
101 difference in genomic structure between the 16 new genome sequences and the known
102 GETV virus, and the nucleotide similarity at the genome-level obtained in this study
103 was 96.98%-99.99%, with reference sequences was 93.99%-99.99%. The similarity
104 between E2 genes obtained in this study at the nucleotide level was 94.24%-100%, and
105 compared with the online reference, the similarity at the nucleotide level was 92.98%-
106 100%. The amino acid similarity was 94.24%-100% and 92.98%-100%, respectively.
107 In addition, the similarity between bovine E2 gene and GETV of infected other species
108 at amino acid level was 94.49%-99.75%, which was the most similar to GETV from
109 *Culex tritaeniorhynchus* Giles. In addition, the similarity between canine E2 gene and
110 GETV infected with other species at amino acid level was 93.48%-100%, which was
111 the most similar to GETV from Pigs.

163 **Supplementary Figures and Tables**

164 **Figure S1.** Environmental factors tested for their impact on the dispersal of GETV
165 lineages in China.

166

167 **Figure S2.** GETV positive cases bar plots. The bar plot under the x-axis represents the
168 number of reported cases of GETV infected mammals in China since 2015. (A) Number
169 of GETV cases in seven regions of China over three time periods from 2015-2017,
170 2018-2019, and 2020-2021. (B) Number of GETV cases in each season from 2015 to
171 2021.

172

173 **Figure S3.** Characterization of GETV in cells and suckling mice. (A) 293T or U251
174 cells were infected with GETV. At 48 hpi, cytopathic changes were observed. (B)
175 Immunofluorescence of GETV Capside protein monoclonal antibody (green) detected
176 in infected 293T or U251 cells, respectively (blue corresponds to DAPI). All fluorescent
177 images were taken at 20× magnification. (C) Weight of mice after infection with GETV.
178 The weight of the mice is plotted against the time of infection. (D) Survival of mice
179 after infection with GETV. No death was detected after 80h in DMEM group but all
180 the suckling mice in the infected group died after 80h. (E) Clinic symptoms of mice
181 after being infected by GETV.

182

183 **Figure S4.** Root-to-tip regression analysis performed with the program TempEst (here
184 best-fitting the root by maximizing the coefficient of determination R^2 of the linear
185 regression).

186

187 **Figure S5.** Comparison of skygrid viral effective population size reconstructions with
188 time-varying covariates. Each plot depicts the mean effective population size trajectory
189 (dark blue), its corresponding 95% highest posterior density interval region (light blue),
190 and a time-varying covariate (dark red). (A) The different covariates are: annual forest
191 area, (B) annual precipitation, (C) annual pork production, and (D) annual mean

192 temperature.

193

194 **Figure S6.** Analysis of lineage dispersal events associated with the maximum clade
195 credibility (MCC) tree obtained from the continuous phylogeographic inference.

196

197 **Table S1.** Positive selected amino acid sites of E2 gene of GETV.

Amino acid site	FEL	SLAC	MEME	FUBAR
86	+	-	+	+
253	-	-	-	+
323	+	-	+	+

198

199 **Table S2.** Impact of several environmental factors on the dispersal location of GETV
200 lineages in China. We report Bayes factor (BF) supports for the association between
201 environmental values and tree node locations. The results are based on 100 posterior
202 trees obtained by spatially-explicit phylogeographic inference. Following Kass &
203 Raftery (1995), we consider a BF value >20 as strong support for a significant
204 correlation between the environmental distances and dispersal durations (in bold).

Environmental factor	Tendency of viral lineages to avoid circulating within specific environmental conditions	Tendency of viral lineages to preferentially circulate within specific environmental conditions
Savannas	0.3	3.5
Forests	0.3	2.9
Croplands	0.1	17.2
Urban areas	0.1	13.3
Elevation	49.0	0.0
Annual mean temperature	0.0	>99
Annual precipitation	0.1	12.3
Pig population density	0.0	>99
