## eMethods

### Statistical Analysis

Network meta-analysis: We conducted a random-effect model network meta-analysis using a consistency model with “netmeta V1.0-1” package under a frequentist framework in R 1.3.1093 software. Frequentist results were shown in league tables. A league table is a square matrix showing all pairwise comparisons in a network meta-analysis. Typically, both treatment estimates and confidence intervals are shown. The netsplit function was used to assess the inconsistency between direct and indirect estimates and obtain indirect effect estimates. Network estimates that have indirect and direct evidence, these estimates are split into three components. The network estimate, indirect estimate and direct estimate are inspected for consistency. Consistency is assessed mainly by inspection of the point estimate and the confidence intervals. P-scores were used to rank each intervention with the interpretation of the mean extent of certainty that one intervention was better than the other. We used contribute plots to presents the contribution of every interventions. This fuction generates the contribution of direct comparisons to every network treatment comparison. The contribution matrix shows how much each direct treatment effect contributes to each treatment effect estimate from network meta-analysis. The output is a matrix where rows represent network treatment effects and columns represent the contribution of direct treatment effects.

Pairwise meta-analyses: Pairwise meta-analyses were performed using RevMan 5.4.1, and the data were synthesized with a random-effects model to obtain direct effect estimates for each pairwise comparison.

Subgroup analysis, meta-regression, and sensitivity analysis: We conducted the subgroup analysis in direct comparisons for a priori specified variables including health status (healthy vs unhealthy, a predefined hypothesis of larger effect in unhealthy population; unhealthy was defined as participants reported having high-risk factors at baseline). We also performed meta-regression in gestational age, and ratio of male and female. Meta-regression is similar to simple regression, where the outcome of interest is predicted on the basis of one or more explanatory variables. Besides, we performed sensitivity analyses to observe the robustness of results by repeating the analyses using a bayesian hierarchical model, and using both fixed-effects model and random-effects model.

## eResults

Network meta-analysis: Frequentist results were shown in league tables (appendix table S7-20). P-scores were used to rank each intervention with the interpretation of the mean extent of certainty that one intervention was better than the other (appendix table S21). The network plots were shown in appendix figure S2-9. The line width is proportional to the number of studies comparing each pair of interventions, and the size of each node is proportional to the number of participants (sample size). The node-split plots were shown in appendix figure S48-61. The contribute plots were shown in appendix figure S62-68, the matrix showed how much each direct treatment effect contributes to each treatment effect estimate from network meta-analysis.

Pairwise meta-analyses: Results of pairwise meta-analyses were shown in forest plots (appendix figure S10-46). Funnel plot of all-cause mortality was presented in appendix figure S47, showing that there may be no publication bias.

Subgroup analysis, meta-regression, and sensitivity analysis: Bayesian results were shown in league tables as sensitivity analyses (appendix table S31-46).

Author, Year	Population	Intervention	Outcome	Study design	Exclude reasons
Ramilo O, 2014	healthy infants	motavizumab	Clinical outcomes data collected included the duration of hospitalization, the need for supplemental oxygen and mechanical ventilation and admission to and length of stay in the intensive care unit (ICU). The incidence of $\geq 1$ or $\geq 3$ medically attended wheezing episodes	RCT	ineligible population
Meissner HC, 1999	preterm infants with or without bronchopulmonary dysplasia (BPD)	SB 209763	laboratory tests, Safety parameters, RSV disease symptoms, Pharmacokinetic parameters	RCT	unable to extract data
Malley R, 1998	RSV infection	palivizumab	serum concentration	RCT	ineligible population
Mori M, 2014	children $\leq 24$ months	palivizumab	rate of RSV-associated hospitalizations occurring, Blood samples, Adverse events	NRCT	wrong study designs
SÁEZ-LLORENS X, 1998	preterm infants with or without bronchopulmonary dysplasia (BPD)	palivizumab	Adverse events, laboratory tests, Pharmacokinetic and immunogenicity assessments	NRCT	wrong study designs
Groothuis JR, 2003	preterm infants	palivizumab	need for hospitalization and hospital course, safety	NRCT	wrong study designs
Brunv, 2000	preterm infants	palivizumab	—	NRCT	wrong study designs
Alansari K, 2019	Infants with a confirmed diagnosis of RSV bronchiolitis	palivizumab	The primary efficacy outcome was readmission to either the infirmary- observation unit, hospital, or PICU during the 3 weeks after discharge. Final secondary outcomes were time to medical readiness for discharge on the initial admission, revisit (but not requiring admission) to any medical facility for the same illness in the 3- week follow-up period, and need for transfer to the PICU during the initial admission	RCT	ineligible population
Alyamovskaya, 2012	50–74 years old participants	long-acting beta-2-agonists	The forced expiratory volume in 1 s (FEV1), Skin blood perfusion changes	RCT	ineligible population
Lagos R, 2009	healthy children aged $< 2$ years (gestational age $> 36$ weeks)	motavizumab	lower respiratory disease scores, the durations of hospitalization, supplemental oxygen use during hospitalization, in- tensive care unit stay, and mechanical ventilation were also recorded. Adverse events (AEs) and serious AEs were monitored through study day 30	RCT	ineligible population
Null D, 2005	Children at 6 selected centers who had participated in Impact-	palivizumab	Adverse events, palivizumab concentrations and anti-palivizumab reactivity	NRCT	wrong study designs

	RSV during the 1996–1997 winter season				
Sáez-Llorens X, 2004	children $\leq 24$ months	palivizumab	RSV hospitalization and for 30 days after study drug administration for safety, determination of drug serum concentration and clinical outcome	RCT	ineligible population
Domachowski J, 2022	preterm infants with heart or lung disease	nirsevimab	Data on adverse events that occurred during treatment and adverse events of special interest were collected through day 361. Pharma cokinetics and antidrug antibody levels were assessed (see Section S3)	NRCT	wrong study designs
Marchac, 2006	—	palivizumab	—	NRCT	wrong study designs
Man WH, 2020	healthy preterm infants; Infants were younger than 6 months of age at the start of the RSV season	palivizumab	primary outcome was to assess the effect of palivizumab during infancy on the respiratory microbiota composition at age 1 year and 6 years; secondary outcomes were assessment of the effect of proven RSV infection in the first year of life on the respiratory microbiota composition at age 1 years and 6 years	RCT	unable to extract data
Makari D, 2014	preterm infants with chronic lung disease	palivizumab liquid	adverse events, Antidrug Antibodies	RCT	ineligible controls
Blanken M, 2012	Healthy preterm infants	palivizumab	The primary endpoint of the study was the number of wheezing days during the first year of life	RCT	unable to extract data

## Appendix table S7-S20: league tables of outcomes in fixed and random models

Outcomes were reported as odds ratio (95% credible interval). All tables list the treatments in alphabetical order. The estimate is in the cell in common between the column-defining intervention and the row-defining intervention. The league table contains the network estimates in the lower triangle and the direct treatment estimates from pairwise comparisons in the upper triangle. The blanks indicate that there is no comparison group for this outcome.

\*Included studies for each outcome assessment:

Author, year	Intervention vs comparison	all-cause mortality	rate of RSV infection	RSV-related hospitalization	rate of ICU admission	rate of mechanical ventilation use	drug-related adverse events	rate of supplemental oxygen use
Griffin, 2020	Nirsevimab vs placebo	√	√	√	√	√	√	√

**Appendix table S21: cumulative ranking of interventions for different outcomes**

Strategies were ranked according to P score, which is the mean extent of certainty that one intervention is better than another, averaged over all competing interventions.

Outcome	Rank	Intervention
Rate of RSV infection	1	Motavizumab
	2	Nirsevimab
	3	Palivizumab
	4	Placebo
	5	Suptavumab
All-cause mortality	1	Nirsevimab
	2	Palivizumab
	3	Motavizumab
	4	M+P
	5	Placebo
RSV-related hospitalization	1	Nirsevimab
	2	Motavizumab
	3	Palivizumab
	4	Suptavumab
	5	Placebo
Rate of supplemental oxygen use	1	Motavizumab
	2	Nirsevimab
	3	Palivizumab
	4	Placebo
Rate of mechanical ventilation use	1	Motavizumab
	2	Palivizumab
	3	Placebo
Rate of ICU admission	1	Motavizumab
	2	Palivizumab
	3	Placebo
Drug-related adverse events	1	M+P
	2	Nirsevimab
	3	Placebo
	4	Suptavumab
	5	Motavizumab
	6	Palivizumab

**Appendix table S30-S45: Bayesian league tables of outcomes in fixed and random models**

Outcomes were reported as odds ratio (95% credible interval). All tables list the treatments in alphabetical order. The estimate is in the cell in common between the column-defining intervention and the row-defining intervention. The league table contains pairwise comparisons of the treatment in the row versus the treatment in the column in the lower triangle and column versus row in the upper triangle.

Treatment effect vs. covariate

Appendix figure S71: meta-regression of publication year in RSV-related hospitalization

Appendix figure S72: Comparison of different monoclonal antibodies on efficacy and safety outcomes

\*The numbers in the circles (light gray) represent the baseline risk, the numbers in the boxes represent the absolute risk of the outcome after using the intervention. For example, the baseline risk of RSV infection was 170 per 1000 participants (light gray), after using nirsevimab, the absolute risk was reduced to 47 per 1000 participants (dark green), which indicates that nirsevimab was the best of the four drugs.

\*AE: adverse events.
