

A**B**

Figure S1. Analysis of redondovirus sequence information; related to Figure 1. (A) Phylogeny of the genomes of 2,164 ssDNA viruses (10 redondovirus genomes and 2,154 genomes of eukaryotic and prokaryotic viruses in the ViPTree ssDNA database; Table S1) based on genome-wide amino-acid sequence similarities in Rep proteins computed by tBLASTx68. iTOL was used for tree visualization and clade collapsing⁵⁵. Colored bands denote virus family or type. Note that redondoviruses cluster distantly in the tree from any annotated ssDNA bacteriophages. (B) Heat map quantifying divergence among known redondovirus Rep protein sequences according to pairwise amino acid distance. RV-30956 is the isolate from the xenic culture described in this work. The R package pheatmap (v1.0.12) was used for figure creation.

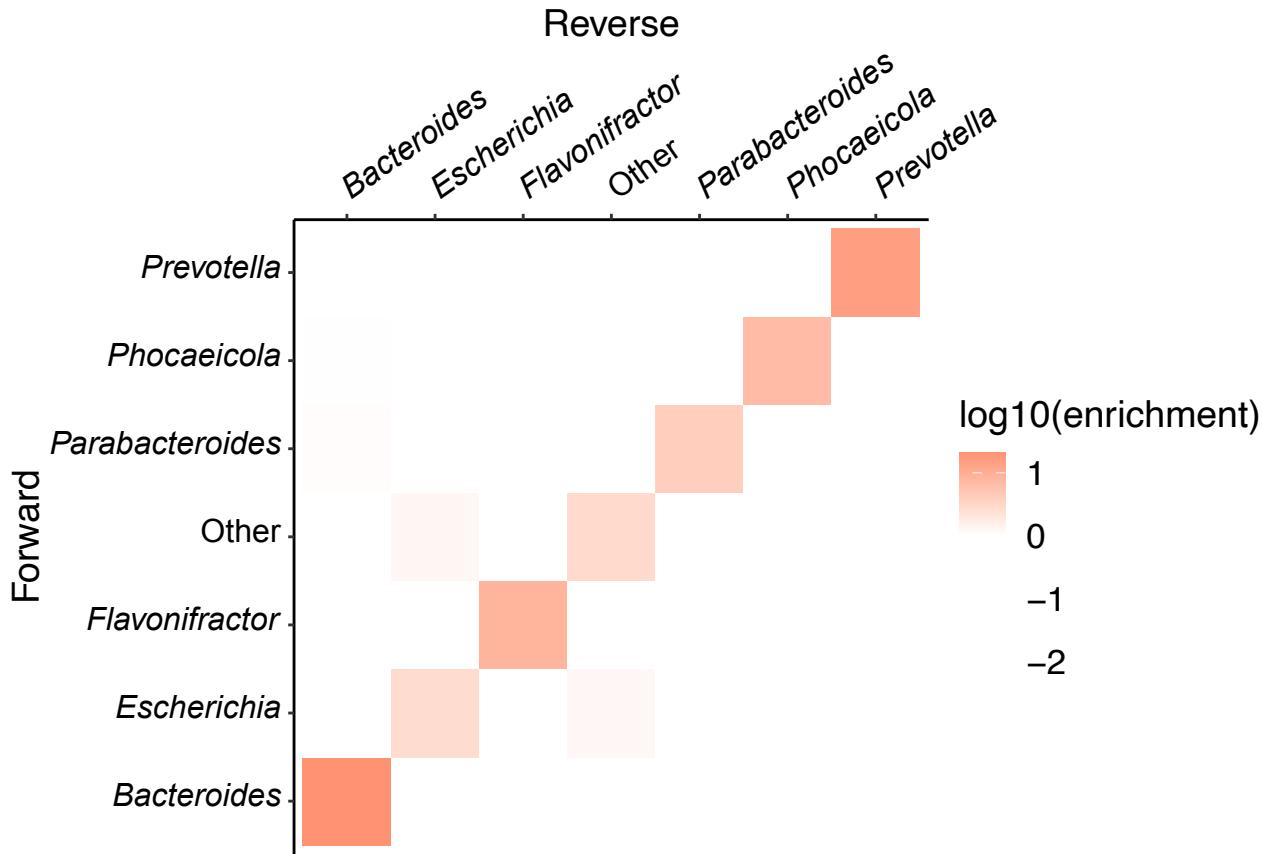

Figure S2. Positive control for the Hi-C data; related to Figure 5. The figure shows the level of enrichment of same species mate pairs in the Hi-C cross-linking data. Taxa are as indicated along the x and y axes and correspond to the most abundant lineages detected in the xenic culture in the metagenomic analysis. Forward indicates forward orientation sequence reads, “reverse” indicates reverse orientation reads. “Other” indicates lineages detected at lower abundances.

Table S2. CRESS virus and putative host genomic GC content; related to Figure 1B.
