

BMJ Open

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email info.bmjopen@bmj.com

Abstract

Objectives Exposures in utero and during infancy may impact the development of diseases later in life. They may be linked with development of frailty though the mechanism is unclear. This study aims to determine the associations between early life risk factors and development of frailty amongst middle-aged and older adults as well as potential pathways via education and socioeconomic factors, for any observed association.

Design A cross-sectional study.

Settings This study used data from UK Biobank, a large population based cohort.

Participants 502,489 individuals aged 37-73 years were included in the analysis.

Primary and secondary outcome measures Early life factors in this study included being breastfed as a baby, maternal smoking, birth weight, the presence of perinatal diseases, birth month, and birth place (in or outside the UK). We developed a frailty index comprising 49 deficits. We used generalised structural equation modelling to examine the associations between early life factors and development of frailty and whether any observed association was mediated via educational attainment and income level.

Results A history of breastfeeding and higher birth weight were associated with a lower frailty index while maternal smoking, the occurrence of perinatal diseases and birth month with a longer day length were associated with a higher frailty index. Both educational level and income mediated the relationship between these early life factors and frailty index.

Conclusions This study highlights that biological and social risk occurring at different stages of life are related to the variations in frailty index in later life and suggests opportunities for prevention across the life course.

Keywords early life factors, frailty, generalised structural equation model, UK Biobank

Article Summary

Strengths and limitations of this study

- Using a large cohort of British adults in middle and older age, this study was sufficiently powered to identify associations between early life factors and frailty index.
- The findings provide the first evidence that education and income mediate the association between early life factors and frailty index.
- As the cohort is not nationally representative, the findings cannot be generalised to the general population.
- The questionnaire on early life factors was based on self-report and is therefore subject to recall error.

Introduction

As the world's population ages, a major goal is the attainment of increased life expectancy accompanied by fewer years spent in poor health and with disability and dependency. The worldwide population of older people (65 years and above) is predicted to double from 0.7 billion (9%) in 2019 to 1.5 billion (16%) in 2050.¹ In addition, there is evidence that the number of disability adjusted life years (DALY) among those aged 60 years and older is increasing (from 434 million in 1990 to 574 million in 2010),² which will increase demand for health and care services. As physical disability is an adverse outcome of frailty,³ more research in geriatrics and gerontology has focused on defining and recognising frailty among older people with the aim of determining preventive and interventional measures.⁴

Frailty can be defined as a state of increased vulnerability resulting from an age-related decline in physiologic and cognitive reserves and function following stressor events.⁵ The frailty index approach, developed by Rockwood et al.,⁶ measures frailty level as the number of deficits present over the number of deficits considered, including symptoms, diagnosis, disabilities, and functional impairments. Frailty has become more common with the ageing of the population. A systematic review including 240 studies from 62 countries showed that 24% of people aged 50 years and older are frail as calculated using the frailty index approach.⁷

Frailty has been found to be associated with adverse health outcomes including loss of mobility, disability, falls, hospitalisation, need for long-term care, and death.⁸⁻¹⁰

Understanding the factors that are associated with frailty is thus important for developing interventions to prevent frailty and for providing directions for future public health policies.

A growing body of literature acknowledges that the first two decades of human life are critical in determining adult life trajectories. Body size at birth has been found to be associated with adult chronic diseases,^{11,12} grip strength¹³ and physical activity.¹⁴ Evidence has suggested that cigarette smoke exposure in utero is linked to the development of chronic diseases later in

1
2
3 life, including type 2 diabetes, obesity, certain cancers and respiratory disorders.¹⁵ Infants
4 exclusively breastfed have been found to have a lower risk of obesity, type 2 diabetes and
5 high blood pressure in adulthood.¹⁶ Studies in the USA¹⁷ and China¹⁸ have discovered a
6 relationship between birth month and the risk of cardiovascular diseases later in life. In the
7 USA, women born in spring and summer were shown to have higher cardiovascular specific
8 mortality rates than those born in the autumn.¹⁷ In a study using patient medical records from
9 the BioBank of First Affiliated Hospital of Xinxiang Medical University patients born in
10 winter were found to have a greater risk of coronary artery disease than those born in spring.¹⁸
11
12 New-borns' perinatal complications are related to accelerated ageing at midlife.¹⁹
13

14
15 There is some evidence also of a link between early life factors and occurrence of frailty. In
16 a recent study in Finland, greater weight, length and BMI at birth were associated with a lower
17 risk of frailty later in life.²⁰ However, data from the Netherlands have suggested no significant
18 association between prenatal undernutrition and frailty among older adults.¹⁴ The present
19 study thus aims to determine the associations between early life factors, including a history
20 of being breastfed, maternal smoking, birth weight, the presence of perinatal diseases, birth
21 in or outside of the UK or outside the UK and birth month, and frailty in UK adults.
22

23
24 Furthermore, this study contributes to the literature investigating the determinants of health
25 in later life by exploring the pathways of early life factors that have a lasting impact on health
26 in middle and old age. The pathway hypothesis posits that early life conditions are important
27 not only because they are directly associated with late life but also because they shape later
28 life experiences,^{21,22} including restricted educational attainment and life chances. The most
29 frequently hypothesised pathway between circumstances in early stages of life and adult
30 health is adult socioeconomic status. Pakpahan et al. showed that education and income
31 mediate the link between childhood health and socioeconomic conditions and self-rated health
32 among older Europeans.²¹ Maternal smoking during pregnancy was found to be correlated

3 with the children's cognitive function,²³ while a longitudinal study in the US documented the
4 relationship between low birth weight and lower educational attainment.²⁴ Education and
5 income are among the predictors of frailty.^{25,26} Because interventions that target common
6 pathways have the potential to reduce frailty, the identification of the pathways of early life
7 factors leading to frailty later in life has substantial public health relevance for the translation
8 of life course epidemiology into practice. The present study considers whether any observed
9 association between early life factors and frailty could be attributed to differences in education
10 attainment and adult socioeconomic status (Figure 1).

21 **Methods**

22 **Source and Sample**

23
24 Data were drawn from the UK Biobank, a prospective cohort study of the genetic,
25 environmental and lifestyle causes of diseases among adults in the UK.²⁷ The study involved
26 the collection of extensive questionnaire data and biological samples from, and the
27 performance of, physical examinations of more than 500,000 respondents enrolled at 22
28 assessment sites in England, Scotland, and Wales between 2006 and 2010. Subjects who took
29 part provided written informed consent for data collection, analysis and linkage; they also
30 completed a touchscreen questionnaire, a nurse-led interview, and had their physical
31 measurements taken. The UK Biobank invited adults who were registered with a general
32 practitioner and who lived within reasonable traveling distance of the assessment centre. The
33 current study includes 502,489 individuals aged 37-73 years who had study-specific available
34 data and were not withdrawn from the study. This study was conducted as part of UK Biobank
35 Project Number 41877 and is covered by the generic ethics approval for UK Biobank studies
36 from the NHS National Research Ethics Service (16/NW/0274).

56 **Measures**

57 *Early life factors*

58
59
60

1
2
3 Information by questionnaire was obtained on: maternal smoking in the pre- and post-natal
4 period, history of being breastfed as a baby, birth month, birthweight, the presence of perinatal
5 diseases, and place of birth. We defined maternal smoking based on the question ‘Did your
6 mother smoke regularly around the time when you were born?’ (Data-Field 1787).
7
8 Respondents were categorised as having been breastfed as babies if they answered ‘yes’ to
9 the question: ‘Were you breastfed when you were a baby?’ (Data-Field 1677). We retrieved
10 information on birth month from the birth date (Data-Field 52) and treated it as the cosine of
11 the values, representing the rhythmic seasonal length of day and night. We considered this
12 might represent daylight time better than treating it as a categorical variable. This is an
13 approach which we have used in a previous study.²⁸ Birth months of participants born in the
14 UK and other countries in the southern hemisphere were converted to their antiphase.
15 Information on birthweight was gathered by means of self-reported birthweight in kilograms
16 (Data-Field 20022). We used the same measure in our prior study.²⁸ The presence of perinatal
17 diseases (‘ICD10 Chapter XVI: Certain conditions originating in the perinatal period’) was
18 coded as one based on self-reported medical history (Category 2416). We categorised the
19 place birth of the respondents as born in the UK or outside the UK (Data-Field 1647). Answers
20 of ‘Do not know’ or ‘Prefer not to answer’ were accepted as missing for all questions.

35
36
37
38
39
40
41

42 *Education*

43
44 The education variable represents the highest educational level completed by the respondents.
45 Qualifications were categorised as high school or less (reference) and college or university
46 degree (Data-Field 6138).
47
48
49
50

51 *Income*

52
53 Income (at the time of the assessment) was determined according to average total household
54 income before tax (Data-Field 738). Income was classified into five ordinal groups: less than
55
56
57
58
59
60

1
2
3 £18,000; £18,000 to £30,999; £31,000 to £51,999; £52,000 to £100,000; and greater than
4
5 £100,000.
6

7 *Frailty index*

8
9
10 Following William et al.,²⁹ we derived the frailty index using 49 functional, psychological,
11
12 and social deficits within the range of data variables in the UK Biobank (see Supplementary
13
14 Table 1). We coded the binary variables as 0 or 1, and for ordinal and continuous variables,
15
16 coding was based on distribution. The total number of deficits was summed and divided by
17
18 total possible deficits to create a frailty index between 0 and 1, where higher scores indicated
19
20 greater frailty.
21
22

23 *Covariates*

24
25 We included demographic and health behaviour as covariates. Demographic information
26
27 included age (in years; Data-Field 21003), gender (with male as the reference; Data-Field 31),
28
29 and ethnicity (other than Caucasian as the reference or Caucasian; Data-Field 21000). Health
30
31 behaviours included physical activity, alcohol intake and smoking status. Physical activity
32
33 was measured as the number of days per week respondents engaged in at least 10 minutes of
34
35 moderate or vigorous physical activity (Data-Field 884, Data-Field 904). Respondents were
36
37 classified as non-current smokers (reference) or current smokers (Data-Field 20116). Alcohol
38
39 intake status was classified as non-current (reference) or current alcohol drinking (Data-Field
40
41 20117).
42
43
44
45

46 **Statistical Analyses**

47
48
49 Descriptive statistics were used to summarise subject characteristics including means and
50
51 standard deviation for continuous variables and frequencies and percentages for categorical
52
53 variables. We looked at the associations between frailty index and both early life factors and
54
55 other covariates using unpaired t-tests (dichotomous variables), ANOVA (categorical
56
57 variables), and Pearson's correlation (continuous variables).
58
59
60

1
2
3 The structural equation model (SEM) has been widely used to investigate complex
4 relationships between variables in epidemiological studies.³⁰ SEM can be used to resolve the
5 endogeneity problem between variables and to explore direct, indirect, and total effects
6 between exogenous and endogenous variables. It can jointly test a variety of hypotheses that
7 involve different types of complicated cause-effect relationships. However, all responses are
8 assumed to be continuous, even when a variable is binary or categorical. In our analysis we
9 include binary (education) and ordinal outcome variables (income). To address this, we used
10 a generalised structural equation model (GSEM) to identify the link between early life factors
11 and frailty index and the mediating effect of education and income on that relationship. A
12 GSEM combines generalised linear model (GLM) estimation and SEM modelling estimation;
13 it can accommodate binary, ordinal, counted and categorical data.³¹ Using maximum
14 likelihood estimators, GLM estimators are based on a density function, allowing the direct
15 use of all types of data.³² The analyses were performed using the 'gsem' command (STATA
16 Version 17).

17 We examined two models. In Model 1, we considered early life factors and frailty index. We
18 then added education and income as mediators of the relationship in Model 2. All models
19 were controlled for age, gender and health behaviours. Modification indices and model fit
20 estimates are not facilitated in the 'gsem' command in STATA. The binary endogenous
21 variable and paths are thus interpreted by their level of significance.

22 We performed two sensitivity analyses. We first performed regression models including early
23 life factors, education, income, and covariates. We further handled missing data using
24 multivariate imputation by chained equations (MICE)³³ (using Stata's mi program).³⁴ Twenty
25 imputations were used. In the second supplementary analysis, we performed the same GSEM
26 models using participants aged 60 years and over.

27 **Patient and public involvement**

1
2
3 Patients and/or the public were not involved in this study.
4

5 **Results**

6 *Subjects*

7
8
9
10 The study sample consisted of 502,489 respondents with an average age of 56.53 years
11 (standard deviation [SD]=8.10 years) (Table 1). Just under half (45%) of the respondents were
12 male, and most were Caucasian (94.59%). Around one-third of the respondents had graduated
13 from college or university. The proportion of respondents whose mothers smoked regularly
14 around the time of their birth was 29%. More than 72% of respondents were breastfed as
15 babies, and 0.18% had perinatal diseases. The average birth weight was 3.32 kg (SD=0.67
16 kg). 91% of the respondents were born in the UK. Just over two-thirds of subjects reported
17 engaging in at least 10 minutes of moderate or vigorous physical activity at least three days
18 per week; 91% consumed alcohol and 10% were current smokers.
19
20
21
22
23
24
25
26
27
28
29

30 *Early life factors, covariates and frailty index*

31
32
33 In bivariate analyses, compared to those whose mothers did not smoke around birth, maternal
34 pre and post-natal smoking was associated with a significantly higher frailty index (0.146 vs
35 0.133) as was the presence of perinatal diseases (0.149 vs 0.138) and being born in the UK
36 (0.138 vs 0.137). A history of breast feeding was associated with a lower frailty index (0.134
37 vs 0.137). Higher birth weight ($r=-0.05$) and shorter daylight hours at birth ($r=-0.01$) were
38 both associated with lower frailty indices. As expected, the frailty index was higher among
39 women than among men and in those with lower educational attainment and lower income.

2
3 with a significantly lower frailty index, while maternal smoking, perinatal diseases and born
4 in the UK had positive and significant associations with frailty index (see Figure 2A).
5
6

7 *Mediation analysis*

8
9
10 In the second model, education and income mediated the association between early life factors
11 and frailty index among middle-aged and older adults, supporting the pathway hypothesis
12 (Figure 2B). The direct effects of early life factors were diminished in comparison to the
13 previous model. Still, the associations between being breastfed as a baby (coef.=-0.0034, z=-
14 9.49), maternal smoking (coef.=0.0116, z=33.02), birthweight (coef.=-0.0023, z=-9.32) and
15 frailty index remained significant after introducing adulthood characteristics. The presence of
16 perinatal diseases (coef.=0.0132, z=3.69) and birth months with long daylight hours (coef.=-
17 0.0007, z=-3.07) had a relatively small though significant effect on frailty (see Supplementary
18 Table 2).
19

21
22
23
24
25
26
27
28
29

30 Education and income mediated the links between early life factors and frailty index.
31 Participants born in the UK had a lower probability of completing higher education (coef.=-
32 0.7993, z=-46.07). Having been breastfed as a baby (coef.=0.1686, z=16.86) and higher birth
33 weight (coef.=0.0779, z=11.11) were associated with higher educational attainment, while
34 maternal smoking was associated with lower educational attainment (coef.=-0.3228, z=-
35 31.43). Higher education was the determinant of income (coef.=1.2703, z=143.32). However,
36 maternal smoking showed no direct relationship with income. Higher birthweight was directly
37 associated with higher income (coef.=0.1312, z=20.46), while having been breastfed as a baby
38 was interestingly associated with lower income (coef.=-0.1086, z=-12.16). Higher average
39 income was significantly associated with a lower frailty index (coef.=-0.0127, z=-84.98).
40 Higher education was also associated with a lower frailty index (coef.=-0.0051, z=-14.64).

2
3 activity levels (coef.=-0.0067, z=-42.98) and smoking (coef.=0.0192, z=35.63) were
4 associated with a higher frailty index.
5
6

7
8 In sensitivity analyses the effects of early life factors and covariates on the frailty index
9 appeared similar in terms of both magnitude and direction when using both non-imputed and
10 imputed data (see Supplementary Table 3). In a further analysis we included participants who
11 were 60 years and older and found that the results were broadly similar (see Supplementary
12 Table 4).

18

19 **Discussions**

20
21 Using data from UK Biobank we found that a history of breastfeeding and higher birth weight
22 were associated with a lower frailty index, while maternal smoking, perinatal diseases and
23 birth month with longer day length were associated with a higher frailty index. This study
24 provides the first evidence that educational attainment level and income may mediate the
25 association between early life factors and frailty index.
26
27
28
29
30
31
32

33 Our findings are in keeping with findings from a previous study linking birth weight and
34 frailty index.²⁰ Our study suggests also an association between other life factors, including
35 maternal smoking, perinatal diseases, and birth month, and frailty index in middle-aged and
36 older adults. Early life factors have previously been linked with higher chronic disease risk
37 later in life.³⁵ Our findings highlight the importance of early life factors in determining frailty
38 in middle age and older men.
39
40
41
42
43
44
45
46

47 The addition of education and income as mediating variables in this study did not annul the
48 direct effect between early life factors and frailty index. The effects of early life factors on the
49 frailty index persist notwithstanding demographic and health behaviours. In line with our
50 findings, Bleker and colleagues found that prenatal undernutrition is associated with poorer
51 health in old age, including slower gait speed and lower physical functioning and the findings
52
53
54
55
56
57
58
59
60

1
2
3 remained significant after inclusion of an extensive set of control variables including adult
4 socioeconomic status.¹⁴
5

6
7
8 In our analysis we observed that education levels mediate the link between early life factors
9 and the frailty index. Early life factors have a significant relationship with educational
10 attainment, and higher education attainment is linked to lower frailty index. This result is
11 broadly in keeping with a prior study in Sweden which found that the associations between
12 childhood conditions and various old age health indicators (musculoskeletal disorders,
13 cardiovascular disease, self-rated health and impaired mobility) are mediated by education.³⁶
14
15 We found that education has also a partly direct and partly indirect association with frailty
16 index through income. This result is consistent with prior research on the biological and
17 psychological pathways that link childhood health and socioeconomic conditions to self-
18 reported health status among older adults in 15 European countries.²¹ Early life health is
19 marked by developmental plasticity; life-course trajectories of socioeconomic attainment
20 could be altered by physical and social conditions³⁷ and set cascading physiological processes
21 in motion, impacting health decades later.³⁸
22
23

24
25
26 Our findings have potential implications for policies aiming at preventing frailty among older
27 adults. Subsequent circumstances mediate the impact of early life factors on frailty later in
28 life, and our study suggests that interventions such as improving education in midlife may
29 mitigate early life disadvantages.
30
31

32
33
34 To our knowledge, this is the first study to examine mechanisms of the relationships between
35 early life factors, i.e. maternal smoking, having been breastfed as a baby, low birth weight,
36 perinatal diseases, and birth month, and the occurrence of frailty. Our findings are based on a
37 large and well characterised cohort. There are, however, a number of limitations to be consider
38 in interpreting the results. In this study, information concerning early life factors was based
39 on self-report and is therefore subject to recall error. The likely effect of such error would be

lifecourse; furthermore, it is possible that the presence of ill health reflected in a higher frailty index may have *resulted* in reduced income rather than being a cause of it. Another limitation is that we have limited access to the health conditions of the parents. A broad range of conditions which are comprised in the frailty index bear a hereditary risk, thus taking in account for the health conditions of the parents is important in assessing the independent associations with frailty. Future studies may include the health conditions of the parents as the covariates. Finally, the data were based on a sample of predominantly Caucasian men and women and should be extrapolated beyond this group with caution.³⁹

In conclusion, this study indicates an association between early life factors and frailty later in life. Early life conditions are important as the start of a mediated, incremental process during the life course. A comprehensive understanding of the determinants of frailty among middle-aged and older adults requires attention to exposures throughout the entire life course, with a special focus on the in utero and infancy stages and the chains of associated socioeconomic conditions that that connect over the life course. Applying a life course perspective on health in adulthood and old age should have implications for public health interventions, social policy, and further research. Early life is not the only period for any potential successful intervention; as our findings show, early life disadvantages may be offset by education and material wealth. Interventions throughout the life course, and especially during early life, could substantially reduce the health burden later in life.

Contributorship statement

A.D and A.M performed the data analysis. A.D and A.M drafted the manuscript. N.P, T.W.O, M.M.C., A.P. and were involved in planning and supervised the work. All authors discussed the results and commented on the manuscript.

Competing interest

All authors declare no conflicts of interest.

Funding

Altug Didikoglu was supported by a grant from the Republic of Turkey Ministry of National Education. This research has been conducted using the UK Biobank Resource under Application Number 41877.

Data sharing statement

Data are available in a public, open access repository. Other researchers can apply for UK Biobank data to answer specific research questions.

Supplementary Material: Pathways linking early life factors and frailty among middle-aged and older adults in England: Findings from UK Biobank

Supplementary Table 1. Variables included in the UK Biobank frailty indices

Item	Variable	Definition	Coding
	Sensory		
1	Glaucoma	Self-report of physician-diagnosed glaucoma	0=no; 1=yes
2	Cataracts	Self-report of physician-diagnosed glaucoma	0=no; 1=yes
3	Hearing difficulty	Self-report experiencing hearing difficulty	0=no; 1=yes/completely deaf
	Cranial		
4	Migraine	Self-report of physician-diagnosed migraine	0=no; 1=yes
5	Dental problems	Self-report of physician-diagnosed dental problems, i.e., ulcers, painful gums, bleeding gums, loose teeth, toothache, dentures	0=none; 1=any
	Mental well-being		
6	Self-rated health	Self-rated health in 4 Likert scale	0=excellent; 0.25=good; 0.5=fair; 1=poor
7	Fatigue	Self-report of frequency of tiredness / lethargy in last two weeks	0=not at all; 0.25=several days; 0.5=more than half; 1=nearly every day
8	Sleep	Self-report experiencing of sleeplessness/ insomnia	0=never/rarely; 0.5=sometimes; 1=usually
9	Depressed feelings	Self-report of frequency having depressed feeling in last two weeks	0=not at all; 0.5=several days; 0.75=more than half; 1=nearly every day
10	Self-described nervous personality	Self-report of having nervous personality	0=no; 1=yes
11	Severe anxiety/ panic attacks	Self-report of physician-diagnosed severe anxiety/panic attacks	0=no; 1=yes
12	Common to feel loneliness	Self-report of feeling lonely commonly	0=no; 1=yes
13	Sense of misery (ever/never)	Self-report of ever having sense of misery	0=no; 1=yes
	Infirmity		
14	Infirmity	Self-report of having long-standing illness or disability	0=no; 1=yes
15	Falls in last year	Self-report of experiencing falls last year	0=no falls; 0.5=one fall; 1=more than one fall
16	Fractures/broken bones in last five years	Self-report of experiencing fractures/broken bones in last five years	0=no; 1=yes
	Cardiometabolic		
17	Diabetes	Self-report of physician-diagnosed diabetes	0=no; 1=yes
18	Myocardial infarction	Self-report of physician-diagnosed myocardial infarction	0=no; 1=yes
19	Angina	Self-report of physician-diagnosed angina	0=no; 1=yes
20	Stroke	Self-report of physician-diagnosed stroke	0=no; 1=yes
21	High blood pressure	Self-report of physician-diagnosed high blood pressure	0=no; 1=yes
22	Hypothyroidism	Self-report of physician-diagnosed hypothyroidism	0=no; 1=yes
23	Deep-vein thrombosis	Self-report of physician-diagnosed deep-vein thrombosis	0=no; 1=yes
24	High cholesterol	Self-report of physician-diagnosed high cholesterol	0=no; 1=yes

	Respiratory		
25	Breathing	Self-report of having wheeze in last year	0=no; 1=yes
26	Pneumonia	Self-report of physician-diagnosed pneumonia	0=no; 1=yes
27	Chronic bronchitis/emphysema	Self-report of physician-diagnosed chronic bronchitis/emphysema	0=no; 1=yes
28	Asthma	Self-report of physician-diagnosed asthma	0=no; 1=yes
	Musculoskeletal		
29	Rheumatoid arthritis	Self-report of physician-diagnosed rheumatoid arthritis	0=no; 1=yes
30	Osteoarthritis	Self-report of physician-diagnosed osteoarthritis	0=no; 1=yes
31	Gout	Self-report of physician-diagnosed gout	0=no; 1=yes
32	Osteoporosis	Self-report of physician-diagnosed osteoporosis	0=no; 1=yes
	Immunological		
33	Hay fever, allergic rhinitis or eczema	Self-report of physician-diagnosed hay fever, allergic rhinitis or eczema	0=no; 1=yes
34	Psoriasis	Self-report of physician-diagnosed psoriasis	0=no; 1=yes
	Cancer		
35	Any cancer diagnosis	Self-report of physician-diagnosed any cancer	0=no; 1=yes
36	Multiple cancers diagnosed (number reported)	Self-report of physician-diagnosed multiple cancer	0=no cancer or single cancer; 1=multiple cancer
	Pain		
37	Chest pain	Self-report of ever experiencing chest pain	0=no; 1=yes
38	Head and/or neck pain	Self-report of ever experiencing head and/or neck pain	0=no; 1=yes
39	Back pain	Self-report of ever experiencing back pain	0=no; 1=yes
40	Stomach/abdominal pain	Self-report of ever experiencing stomach/abdominal pain	0=no; 1=yes
41	Hip pain	Self-report of ever experiencing hip pain	0=no; 1=yes
42	Knee pain	Self-report of ever experiencing knee pain	0=no; 1=yes
43	Whole-body pain	Self-report of ever experiencing whole-body pain	0=no; 1=yes
44	Facial pain	Self-report of ever experiencing facial pain	0=no; 1=yes
45	Sciatica	Self-report of physician-diagnosed sciatica	0=no; 1=yes
	Gastrointestinal		
46	Gastric reflux	Self-report of physician-diagnosed gastric reflux	0=no; 1=yes
47	Hiatus hernia	Self-report of physician-diagnosed hiatus hernia	0=no; 1=yes
48	Gall stones	Self-report of physician-diagnosed gall stones	0=no; 1=yes
49	Diverticulitis	Self-report of physician-diagnosed diverticulitis	0=no; 1=yes

Notes: Deficit points are summed for each individual, and divided by the total number of deficits, to produce a frailty index with a range from 0 to 1.

Generalized structural equation models: Frailty (Gaussian; identity), Education (Bernoulli, logit), Income (Ordinal, logit).

Model 1 includes early life predictors controlled with age, gender, ethnicity, smoking, alcohol drinking and physical activity covariates. Model 2 includes early life predictors controlled with age, gender, ethnicity, smoking, alcohol drinking and physical activity covariates, and education and income mediators.

Supplementary Table 3. Sensitivity analysis: Regression models predicting frailty index

	Non-imputed data ¹ (n=190,575)	Imputed data ¹ (n=502,489)

Generalized structural equation models: Frailty (Gaussian; identity), Education (Bernoulli, logit), Income (Ordinal, logit).

Model 1 includes early life predictors controlled with age, gender, ethnicity, smoking, alcohol drinking and physical activity covariates. Model 2 includes early life predictors controlled with age, gender, ethnicity, smoking, alcohol drinking and physical activity covariates, and education and income mediators.

Reporting checklist for cross sectional study.

Based on the STROBE cross sectional guidelines.

Instructions to authors

Complete this checklist by entering the page numbers from your manuscript where readers will find each of the items listed below.

Your article may not currently address all the items on the checklist. Please modify your text to include the missing information. If you are certain that an item does not apply, please write "n/a" and provide a short explanation.

Upload your completed checklist as an extra file when you submit to a journal.

In your methods section, say that you used the STROBE cross sectional reporting guidelines, and cite them as:

von Elm E, Altman DG, Egger M, Pocock SJ, Gotsche PC, Vandenbroucke JP. The Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) Statement: guidelines for reporting observational studies.

Title and abstract			
Title	#1a	Indicate the study's design with a commonly used term in the title or the abstract	1
Abstract	#1b	Provide in the abstract an informative and balanced summary	3

of what was done and what was found

Introduction

Background / rationale	#2	Explain the scientific background and rationale for the investigation being reported	4
Objectives	#3	State specific objectives, including any prespecified hypotheses	6
Methods			
Study design	#4	Present key elements of study design early in the paper	7
Setting	#5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	7
Eligibility criteria	#6a	Give the eligibility criteria, and the sources and methods of selection of participants.	7
	#7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	8-9
Data sources / measurement	#8	For each variable of interest give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group. Give information separately for for exposed and unexposed groups if applicable.	9
Bias	#9	Describe any efforts to address potential sources of bias	10
Study size	#10	Explain how the study size was arrived at	8

1	Quantitative	#11	Explain how quantitative variables were handled in the	8-9
2				
3	variables		analyses. If applicable, describe which groupings were chosen,	
4				
5			and why	
6				
7				
8				
9	Statistical	#12a	Describe all statistical methods, including those used to control	9-10

Abstract

Objectives Exposures in utero and during infancy may impact the development of diseases later in life. They may be linked with development of frailty though the mechanism is unclear. This study aims to determine the associations between early life risk factors and development of frailty amongst middle-aged and older adults as well as potential pathways via education, for any observed association.

Design A cross-sectional study.

Settings This study used data from UK Biobank, a large population-based cohort.

Participants 502,489 individuals aged 37-73 years were included in the analysis.

Primary and secondary outcome measures Early life factors in this study included being breastfed as a baby, maternal smoking, birth weight, the presence of perinatal diseases, birth month, and birth place (in or outside the UK). We developed a frailty index comprising 49 deficits. We used generalised structural equation modelling to examine the associations between early life factors and development of frailty and whether any observed association was mediated via educational attainment.

Results A history of breastfeeding and higher birth weight were associated with a lower frailty index while maternal smoking, the occurrence of perinatal diseases and birth month with a longer day length were associated with a higher frailty index. Educational level mediated the relationship between these early life factors and frailty index.

Conclusions This study highlights that biological and social risk occurring at different stages of life are related to the variations in frailty index in later life and suggests opportunities for prevention across the life course.

Keywords early life factors, frailty, generalised structural equation model, UK Biobank

Article Summary

Strengths and limitations of this study

- Using a large cohort of British adults in middle and older age, this study was sufficiently powered to identify associations between early life factors and frailty index.
- The findings provide the first evidence that education mediates the association between early life factors and frailty index.
- As the cohort is not nationally representative, the findings cannot be generalised to the general population.
- The questionnaire on early life factors was based on self-report and is therefore subject to recall error.

Introduction

As the world's population ages, a major goal is the attainment of increased life expectancy accompanied by fewer years spent in poor health and with disability and dependency. The worldwide population of older people (65 years and above) is predicted to double from 0.7 billion (9%) in 2019 to 1.5 billion (16%) in 2050 [1]. In addition, there is evidence that the number of disability adjusted life years (DALY) among those aged 60 years and older is increasing (from 434 million in 1990 to 574 million in 2010) [2], which will increase demand for health and care services. As physical disability is an adverse outcome of frailty [3], more research in geriatrics and gerontology has focused on defining and recognising frailty among older people with the aim of determining preventive and interventional measures [4].

Frailty can be defined as a state of increased vulnerability resulting from an age-related decline in physiologic and cognitive reserves and function following stressor events [5]. The frailty index approach, developed by Rockwood et al. [6], measures frailty level as the number of deficits presents over the number of deficits considered, including symptoms, diagnoses, disabilities, and functional impairments. Frailty has become more common with the ageing of the population. A systematic review including 240 studies from 62 countries showed that 24% of people aged 50 years and older are frail as calculated using the frailty index approach [7].

Frailty has been found to be associated with adverse health outcomes including loss of mobility, disability, falls, hospitalisation, need for long-term care, and death [8-10].

Understanding the factors that are associated with frailty is thus important for developing interventions to prevent frailty and for providing directions for future public health policies.

A growing body of literature acknowledges that the first two decades of human life are critical in determining adult life trajectories. Among the early life factors, body size at birth [11-12], cigarette smoke exposure in utero [13], infants exclusively breastfed [14], birth month [15], and the presence of perinatal diseases [16] have been found to be associated with adult chronic

1
2
3 diseases. However, the study linking those factors and frailty is limited. In addition, the
4
5 evidence on the link between early life factors and occurrence of frailty have been mixed
6
7 [17,18]. The present study thus aims to determine the associations between early life factors,
8
9 including a history of being breastfed, maternal smoking, birth weight, the presence of
10
11 perinatal diseases, birth in or outside of the UK or outside the UK and birth month, and frailty
12
13 in UK adults.
14
15

16
17 Furthermore, this study contributes to the literature investigating the determinants of health
18
19 in later life by exploring the pathways of early life factors that have a lasting impact on health
20
21 in middle and old age. The pathway hypothesis posits that early life conditions are important
22
23 not only because they are directly associated with late life but also because they shape later
24
25 life experiences [19,20], including restricted educational attainment and life chances. The
26
27 most frequently hypothesised pathway between circumstances in early stages of life and adult
28
29 health is adult socioeconomic status. Pakpahan et al. showed that socioeconomic factors in
30
31 adulthood, including education, mediate the link between childhood health and
32
33 socioeconomic conditions and self-rated health among older Europeans [19]. Because
34
35 interventions that target common pathways have the potential to reduce frailty, the
36
37 identification of the pathways of early life factors leading to frailty later in life has substantial
38
39 public health relevance for the translation of life course epidemiology into practice. The
40
41 present study considers whether any observed association between early life factors and frailty
42
43 could be attributed to differences in education attainment (Figure 1).

49 **Methods**

50 **Source and Sample**

51
52 Data were drawn from the UK Biobank, a prospective cohort study of the genetic,
53
54 environmental and lifestyle causes of diseases among adults in the UK [21]. The study
55
56 involved the collection of extensive questionnaire data and biological samples from, and the
57
58
59
60

1
2
3 performance of, physical examinations of more than 500,000 respondents enrolled at 22
4 assessment sites in England, Scotland, and Wales between 2006 and 2010. Subjects who took
5 part provided written informed consent for data collection, analysis and linkage; they also
6 completed a touchscreen questionnaire, a nurse-led interview, and had their physical
7 measurements taken. The UK Biobank invited adults who were registered with a general
8 practitioner and who lived within reasonable traveling distance of the assessment centre. The
9 current study includes 502,489 individuals aged 37-73 years who had study-specific available
10 data and were not withdrawn from the study. This study was conducted as part of UK Biobank
11 Project Number 41877 and is covered by the generic ethics approval for UK Biobank studies
12 from the NHS National Research Ethics Service (16/NW/0274).

26 **Measures**

28 *Early life factors*

30 Information by questionnaire was obtained on: maternal smoking in the pre- and post-natal
31 period, history of being breastfed as a baby, birth month, birthweight, the presence of perinatal
32 diseases, and place of birth. We defined maternal smoking based on the question ‘Did your
33 mother smoke regularly around the time when you were born?’ (Data-Field 1787).
34 Respondents were categorised as having been breastfed as babies if they answered ‘yes’ to
35 the question: ‘Were you breastfed when you were a baby?’ (Data-Field 1677). We retrieved
36 information on birth month from the birth date (Data-Field 52) and treated it as the cosine of
37 the values, representing the rhythmic seasonal length of day and night. We considered this
38 might represent daylight time better than treating it as a categorical variable. This is an
39 approach which we have used in a previous study [22]. Birth months of participants born in
40 the UK and other countries in the southern hemisphere were converted to their antiphase.
41 Information on birthweight was gathered by means of self-reported birthweight in kilograms
42 (Data-Field 20022). We categorised the birth weight into low birth weight (<2,500 g), normal

3 birth weight (2,500 – 4,000), and high birth weight (>4,000 gr). The presence of perinatal
4 diseases ('ICD10 Chapter XVI: Certain conditions originating in the perinatal period') was
5 coded as one based on self-reported medical history (Category 2416). We categorised the
6 place birth of the respondents as born in the UK or outside the UK (Data-Field 1647). Answers
7 of 'Do not know' or 'Prefer not to answer' were accepted as missing for all questions.
8
9

10 11 12 13 14 *Education*

15
16 The education variable represents the highest educational level completed by the respondents.
17 Qualifications were categorised as high school or less (reference) and college or university
18 degree (Data-Field 6138).
19
20
21
22

23 24 *Frailty index*

25
26 Following William et al. [23], we derived the frailty index using 49 functional, psychological,
27 and social deficits within the range of data variables in the UK Biobank (see Supplementary
28 Table 1). We coded the binary variables as 0 or 1, and for ordinal and continuous variables,
29 coding was based on distribution. The total number of deficits was summed and divided by
30 total possible deficits to create a frailty index between 0 and 1, where higher scores indicated
31 greater frailty.
32
33
34
35
36
37
38

39 40 *Covariates*

41
42 We included demographic and health behaviour as covariates. Demographic information
43 included age (in years; Data-Field 21003), gender (with male as the reference; Data-Field 31),
44 and ethnicity (other than Caucasian as the reference or Caucasian; Data-Field 21000). Health
45 behaviours included physical activity, alcohol intake and smoking status. Physical activity
46 was measured as the number of days per week respondents engaged in at least 10 minutes of
47 moderate or vigorous physical activity (Data-Field 884, Data-Field 904). Respondents were
48 classified as non-current smokers (reference) or current smokers (Data-Field 20116). Alcohol
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 intake status was classified as non-current (reference) or current alcohol drinking (Data-Field
4
5 20117).
6

7 8 **Statistical Analyses** 9

10 Descriptive statistics were used to summarise subject characteristics including means and
11
12 standard deviation for continuous variables and frequencies and percentages for categorical
13
14 variables. We looked at the associations between frailty index and both early life factors and
15
16 other covariates using unpaired t-tests (dichotomous variables), ANOVA (categorical
17
18 variables), and Pearson's correlation (continuous variables).
19

20
21 We first performed a multivariate regression model including early life factors, education, and
22
23 covariates (age, gender, ethnicity, smoking, alcohol drinking, physical activity). We further
24
25 handled missing data using multivariate imputation by chained equations (MICE) [24] (using
26
27 Stata's mi program) [25]. Twenty imputations were used.
28
29

30 The structural equation model (SEM) has been widely used to investigate complex
31
32 relationships between variables in epidemiological studies [26]. SEM can be used to resolve
33
34 the endogeneity problem between variables and to explore direct, indirect, and total effects
35
36 between exogenous and endogenous variables. It can jointly test a variety of hypotheses that
37
38 involve different types of complicated cause-effect relationships. However, all responses are
39
40 assumed to be continuous, even when a variable is binary or categorical. In our analysis we
41
42 include binary (education). To address this, we used a generalised structural equation model
43
44 (GSEM) to identify the link between early life factors and frailty index and the mediating
45
46 effect of education and income on that relationship. A GSEM combines generalised linear
47
48 model (GLM) estimation and SEM modelling estimation; it can accommodate binary, ordinal,
49
50 counted and categorical data [27]. Using maximum likelihood estimators, GLM estimators
51
52 are based on a density function, allowing the direct use of all types of data [28]. The analyses
53
54 were performed using MPlus version 8. We examined education as mediators of the
55
56
57
58
59
60

1
2
3 relationship in the GSEM model, which were controlled for age, gender, ethnicity and health
4 behaviours (Model fit information: Chi-square=5049.35, p value=0.00; RMSEA=0.06,
5
6 CFI=0.82; WRMR=13.01).
7
8

9 10 **Patient and public involvement**

11
12 Patients and/or the public were not involved in this study.
13

14 15 **Results**

16 17 *Subjects*

18
19 The study sample consisted of 502,489 respondents with an average age of 56.53 years
20 (standard deviation [SD]=8.10 years) (Table 1). Just under half (45%) of the respondents were
21 male, and most were Caucasian (94.59%). Around one-third of the respondents had graduated
22 from college or university. The proportion of respondents whose mothers smoked regularly
23 around the time of their birth was 29%. More than 72% of respondents were breastfed as
24 babies, and 0.18% had perinatal diseases. 10% of respondents had low birth weight, while
25 13% of them had high birth weight. 91% of the respondents were born in the UK. Just over
26 two-thirds of subjects reported engaging in at least 10 minutes of moderate or vigorous
27 physical activity at least three days per week; 92% consumed alcohol and 11% were current
28 smokers.

35
36
37
38
39
40
41

42 43 *Early life factors, covariates and frailty index*

44
45 In bivariate analyses, compared to those whose mothers did not smoke around birth, maternal
46 pre- and post-natal smoking was associated with a significantly higher frailty index (0.146 vs
47 0.133) as was the presence of perinatal diseases (0.149 vs 0.138) and being born in the UK
48 (0.138 vs 0.137). A history of breast feeding was associated with a lower frailty index (0.134
49 vs 0.137). Low (0.149 vs 0.131) and high (0.136 vs 0.138) birthweight were associated with
50 higher frailty scores compared to normal birthweight. Shorter daylight hours at birth ($r=-0.01$)
51 were associated with lower frailty indices. As expected, the frailty index was higher among
52
53
54
55
56
57
58
59
60

1
2
3 women than among men and in those with lower educational attainment. The frailty index
4
5 was also higher in smokers, non-drinkers and those who engaged in less physical activity.
6

7
8 In regression analyses the effects of early life factors and covariates on the frailty index
9
10 appeared similar in terms of both magnitude and direction when using both non-imputed and
11
12 imputed data (see Supplementary Table 2). In these multivariate regression analyses adjusting
13
14 for age, gender and health behaviours, birth month with longer hours of daylight, having a
15
16 low and high birthweight, maternal smoking, being breastfed as baby, perinatal diseases and
17
18 born in the UK had positive and significant associations with frailty index.
19

20 21 *Mediation analysis*

22
23 In the GSEM model, education mediated the association between early life factors and frailty
24
25 index among middle-aged and older adults, supporting the pathway hypothesis. Table 2
26
27 presents the total, direct and indirect effects for each of the early life factor on the frailty
28
29 index. Maternal smoking (direct effect: coef.=0.068, z=33.40; indirect effect: coef.=0.011,
30
31 z=25.54) and low (direct effect: coef.=0.041, z=20.93; indirect effect: coef.=0.003, z=9.18)
32
33 and high birthweight (direct effect: coef.=0.013, z=6.34; indirect effect: coef.=0.001, z=4.09)
34
35 were directly and indirectly affecting frailty index compared to normal birthweight. The direct
36
37 and indirect effects of breastfed as a baby on lower frailty index were -0.022 (z=-10.36) and
38
39 -0.009 (z=-22.91). Perinatal diseases had significant direct effect on higher frailty index
40
41 (coef.=0.007, z=3.83), but it had no indirect effect on the frailty index (coef.=0.000, z=0.27).
42
43 Born in the UK, differently, had significant indirect effect on higher frailty index
44
45 (coef.=0.016, z=31.24), but it had no direct effect on the frailty index (coef.=0.002, z=0.74).
46
47 Birth months with short daylight was affecting lower frailty scores with the lowest effect size
48
49 both directly (coef.=-0.006, z=-2.91) and indirectly (coef.=-0.001, p-value=-2.35).
50
51 Education mediated the links between early life factors and frailty index (Figure 2).
52
53 Participants born in the UK had a lower probability of completing higher education (coef.=
54
55
56
57
58
59
60

0.130, $z=-44.65$). Having been breastfed as a baby (coef.=0.076, $z=26.87$) were associated with higher educational attainment, while maternal smoking was associated with lower educational attainment (coef.=-0.087, $z=-31.41$). Had low (coef.=-0.027, $z=-9.39$) and high birthweight (coef.=-0.011, $z=-4.11$) was related to lower education attainment compared to normal birthweight. Birth months with short daylight was related to higher education with the lowest effect size (coef.=0.006, $z=2.35$). Higher education was also associated with a lower frailty index (coef.=-0.123, $z=-44.30$). Amongst covariates with greater effect sizes, older age (coef.=0.178, $z=83.25$), lower activity levels (coef.=-0.088, $z=-45.61$) and smoking (coef.=0.106, $z=56.36$) were associated with a higher frailty index. Drinking alcohol is related to lower frailty index (coef.=-0.093; $z=-51.63$).

Discussions

Using data from UK Biobank we found that a history of breastfeeding was associated with a lower frailty index, while maternal smoking, having low or high birth weight, perinatal diseases and birth month with longer day length were associated with a higher frailty index. This study provides the first evidence that educational attainment level mediates the association between early life factors and frailty index.

Early life factors have previously been linked with higher frailty and chronic disease risk later in life [29,30]. Our findings highlight the importance of early life factors in determining frailty in middle age and older individuals. Maternal smoking was directly associated with higher frailty compared to those who were not exposed to maternal smoking. Evidence has suggested that cigarette smoke exposure in utero is linked to the development of chronic diseases later in life, including type 2 diabetes, obesity, certain cancers and respiratory disorders [13]. We also showed that this association was mediated by educational attainment. This is in line with a previous study which reported lower academic achievements of adolescents whose mothers

1
2
3 smoked during pregnancy [31]. Maternal smoking during pregnancy was also found to be
4 correlated with the children's cognitive function [32].
5
6

7
8 There is some evidence of a link between early life factors and occurrence of frailty. In a
9
10 recent study in Finland, greater weight, length and BMI at birth were associated with a lower
11 risk of frailty later in life [17]. Having low or high birth weight were associated with higher
12 frailty index compared to had normal birthweight, both directly and indirectly through
13 education. Bleker and colleagues found that prenatal undernutrition was not associated with
14 frailty but was associated with poorer health in old age, including slower gait speed and lower
15 physical functioning and the findings remained significant after inclusion of an extensive set
16 of control variables including adult socioeconomic status [18]. Low birth weight is associated
17 with increased risk of age-related diseases in prior review, and insulin-like growth factor
18 (IGF-1) is the key driver of this process [33]. High birth weight may be the results of maternal
19 obesity,³⁴ and a study in Finland found that being born large for gestational age at term was
20 associated with thicker carotid intima medial as the marker of subclinical atherosclerosis [35].
21 We also found that individuals who reported that they were breastfed have lower frailty score.
22 Infants exclusively breastfed have been found to have a lower risk of obesity, type 2 diabetes
23 and high blood pressure in adulthood [14].

42 Birth months is associated with lower frailty index with a limited effect sizes in our study. In a
43 large study in the US with 1,749,400 individuals showed that spring summer-born individual
44 have relatively higher risk than autumn-winter born individuals and these seasons coincide
45 with lower life expectancy [36]. This study showed that not only cardiovascular diseases but
46 also several chronic diseases were found associated with season of birth with having a
47 different seasonal pattern. The underlying mechanisms may differ for each of these
48 associations such as sensitization to allergens or vitamin D deficiency [36]. Another possible
49 mechanism is that differential light exposure during perinatal period influences development
50

55
56
57
58
59
60

1
2
3 of the biological clock, in turn influencing later-life circadian rhythms and sleep system which
4 are essential for health [37]. In European countries, it was shown that spring/summer born
5 participants compared to autumn had higher frailty score but this effect seemed independent
6 of education [38]. However, we found an indirect effect of season of birth through education.
7
8 the indirect relationship of season of birth and frailty may be due to social factors such as
9
10 September date cut-off to determine age when they start education, which is in line with our
11 findings showing an association between winter-born individuals and higher education
12 [39,40].

13
14
15 Our results further suggest that having a perinatal disease was associated directly with higher
16 frailty index. New-borns' perinatal complications are related to accelerated ageing at midlife
17 [16]. Being born in the UK only affecting the frailty index indirectly through education, but
18 not directly. Respondents who were not born in the UK were likely to have higher education
19 attainment, which in turn able to better maintain their health during in later stage of their lives.
20
21 However, we should note that our sample in this analysis may not be the representation
22 of general population and that participants were categorised as being born outside UK without
23 taking into account the country of origin and their background. In our analysis we observed
24 that education levels mediate the link between the other early life factors and the frailty index.
25
26 Early life factors have a significant relationship with educational attainment, and higher
27 education attainment is linked to lower frailty index. This result is broadly in keeping with a
28 prior study in Sweden which found that the associations between childhood conditions and
29 various old age health indicators (musculoskeletal disorders, cardiovascular disease, self-
30 rated health and impaired mobility) are mediated by education [41]. Prior research on the
31 biological and psychological pathways linked childhood health and socioeconomic conditions
32 to self-reported health status among older adults in 15 European countries [19]. Early life
33 health is marked by developmental plasticity; life-course trajectories of socioeconomic

1
2
3 attainment could be altered by physical and social conditions [42] and set cascading
4 physiological processes in motion, impacting health decades later [43]. Our findings have
5 potential implications for policies aiming at preventing frailty among older adults. Subsequent
6 circumstances mediate the impact of early life factors on frailty later in life, and our study
7 suggests that interventions such as improving education in midlife may mitigate early life
8 disadvantages.

9
10 Our findings are based on a large and well characterised cohort. There are, however, a number
11 of limitations to be consider in interpreting the results. First, information concerning early life
12 factors in this study was based on self-report and is therefore subject to recall error. The likely
13 effect of such error would be to underestimate the relationship between these factors and the
14 frailty index. Second, we have limited access to the health conditions of the parents. A broad
15 range of conditions which are comprised in the frailty index bear a hereditary risk, thus taking
16 into account the health conditions of the parents is important in assessing the independent
17 associations with frailty. Future studies may include the health conditions of the parents as
18 the covariates. Third, the information on breast feeding duration is unavailable. Breast feeding
19 for weeks rather than months may confer different outcomes. A dose response relationship is
20 thus cannot be assessed. Finally, the data were based on a sample of predominantly Caucasian
21 men and women and should be extrapolated beyond this group with caution [44].

22
23 In conclusion, this study indicates an association between early life factors and frailty later in
24 life. Early life conditions are important as the start of a mediated, incremental process during
25 the life course. A comprehensive understanding of the determinants of frailty among middle-
26 aged and older adults requires attention to exposures throughout the entire life course, with a
27 special focus on the in utero and infancy stages and the chains of associated socioeconomic
28 conditions that that connect over the life course. Applying a life course perspective to health
29 in adulthood and old age should have implications for public health interventions, social
30

1
2
3 policy, and further research. Early life is not the only period for any potential successful
4
5 intervention; as our findings show, early life disadvantages may be offset by education and
6
7 material wealth. Interventions throughout the life course, and especially during early life,
8
9 could substantially reduce the health burden later in life.

The pathways of early life factors and impact on frailty among adults

274x190mm (277 x 277 DPI)

Generalised structural equation models to identify the association between early life factors and frailty index, and education as mediators of the relationship between early life factors and frailty index. Note: *Significant at 0.05; † Significant at 0.0001

274x190mm (277 x 277 DPI)

Supplementary Material: Pathways linking early life factors and frailty among middle-aged and older adults in England: Findings from UK Biobank

Supplementary Table 1. Variables included in the UK Biobank frailty indices

Item	Variable	Definition	Coding
	Sensory		
1	Glaucoma	Self-report of physician-diagnosed glaucoma	0=no; 1=yes
2	Cataracts	Self-report of physician-diagnosed glaucoma	0=no; 1=yes
3	Hearing difficulty	Self-report experiencing hearing difficulty	0=no; 1=yes/completely deaf
	Cranial		
4	Migraine	Self-report of physician-diagnosed migraine	0=no; 1=yes
5	Dental problems	Self-report of physician-diagnosed dental problems, i.e., ulcers, painful gums, bleeding gums, loose teeth, toothache, dentures	0=none; 1=any
	Mental well-being		
6	Self-rated health	Self-rated health in 4 Likert scale	0=excellent; 0.25=good; 0.5=fair; 1=poor
7	Fatigue	Self-report of frequency of tiredness / lethargy in last two weeks	0=not at all; 0.25=several days; 0.5=more than half; 1=nearly every day
8	Sleep	Self-report experiencing of sleeplessness/ insomnia	0=never/rarely; 0.5=sometimes; 1=usually
9	Depressed feelings	Self-report of frequency having depressed feeling in last two weeks	0=not at all; 0.5=several days; 0.75=more than half; 1=nearly every day
10	Self-described nervous personality	Self-report of having nervous personality	0=no; 1=yes
11	Severe anxiety/ panic attacks	Self-report of physician-diagnosed severe anxiety/panic attacks	0=no; 1=yes
12	Common to feel loneliness	Self-report of feeling lonely commonly	0=no; 1=yes
13	Sense of misery (ever/never)	Self-report of ever having sense of misery	0=no; 1=yes
	Infirmity		
14	Infirmity	Self-report of having long-standing illness or disability	0=no; 1=yes
15	Falls in last year	Self-report of experiencing falls last year	0=no falls; 0.5=one fall; 1=more than one fall
16	Fractures/broken bones in last five years	Self-report of experiencing fractures/broken bones in last five years	0=no; 1=yes
	Cardiometabolic		
17	Diabetes	Self-report of physician-diagnosed diabetes	0=no; 1=yes
18	Myocardial infarction	Self-report of physician-diagnosed myocardial infarction	0=no; 1=yes
19	Angina	Self-report of physician-diagnosed angina	0=no; 1=yes
20	Stroke	Self-report of physician-diagnosed stroke	0=no; 1=yes
21	High blood pressure	Self-report of physician-diagnosed high blood pressure	0=no; 1=yes
22	Hypothyroidism	Self-report of physician-diagnosed hypothyroidism	0=no; 1=yes
23	Deep-vein thrombosis	Self-report of physician-diagnosed deep-vein thrombosis	0=no; 1=yes
24	High cholesterol	Self-report of physician-diagnosed high cholesterol	0=no; 1=yes

	Respiratory		
25	Breathing	Self-report of having wheeze in last year	0=no; 1=yes
26	Pneumonia	Self-report of physician-diagnosed pneumonia	0=no; 1=yes
27	Chronic bronchitis/emphysema	Self-report of physician-diagnosed chronic bronchitis/emphysema	0=no; 1=yes
28	Asthma	Self-report of physician-diagnosed asthma	0=no; 1=yes
	Musculoskeletal		
29	Rheumatoid arthritis	Self-report of physician-diagnosed rheumatoid arthritis	0=no; 1=yes
30	Osteoarthritis	Self-report of physician-diagnosed osteoarthritis	0=no; 1=yes
31	Gout	Self-report of physician-diagnosed gout	0=no; 1=yes
32	Osteoporosis	Self-report of physician-diagnosed osteoporosis	0=no; 1=yes
	Immunological		
33	Hay fever, allergic rhinitis or eczema	Self-report of physician-diagnosed hay fever, allergic rhinitis or eczema	0=no; 1=yes
34	Psoriasis	Self-report of physician-diagnosed psoriasis	0=no; 1=yes
	Cancer		
35	Any cancer diagnosis	Self-report of physician-diagnosed any cancer	0=no; 1=yes
36	Multiple cancers diagnosed (number reported)	Self-report of physician-diagnosed multiple cancer	0=no cancer or single cancer; 1=multiple cancer
	Pain		
37	Chest pain	Self-report of ever experiencing chest pain	0=no; 1=yes
38	Head and/or neck pain	Self-report of ever experiencing head and/or neck pain	0=no; 1=yes
39	Back pain	Self-report of ever experiencing back pain	0=no; 1=yes
40	Stomach/abdominal pain	Self-report of ever experiencing stomach/abdominal pain	0=no; 1=yes
41	Hip pain	Self-report of ever experiencing hip pain	0=no; 1=yes
42	Knee pain	Self-report of ever experiencing knee pain	0=no; 1=yes
43	Whole-body pain	Self-report of ever experiencing whole-body pain	0=no; 1=yes
44	Facial pain	Self-report of ever experiencing facial pain	0=no; 1=yes
45	Sciatica	Self-report of physician-diagnosed sciatica	0=no; 1=yes
	Gastrointestinal		
46	Gastric reflux	Self-report of physician-diagnosed gastric reflux	0=no; 1=yes
47	Hiatus hernia	Self-report of physician-diagnosed hiatus hernia	0=no; 1=yes
48	Gall stones	Self-report of physician-diagnosed gall stones	0=no; 1=yes
49	Diverticulitis	Self-report of physician-diagnosed diverticulitis	0=no; 1=yes

Notes: Deficit points are summed for each individual, and divided by the total number of deficits, to produce a frailty index with a range from 0 to 1.

Supplementary Table 2. Regression models predicting frailty index

	Non-imputed data¹	Imputed data¹
	(n=190,575)	(n=502,489)

Intercept	0.0976 (0.0947,0.1005)†	0.0998 (0.0972,0.1024)†

Note: ¹ presented are coefficients (95% confidence intervals); *Significant at 0.05; † Significant at 0.0001. Non-imputed analysis was based on 214,104 respondents with complete information on all variables. The maternal smoking variable includes 13.86% missing data, the breastfed as a baby variable includes 23.64% missing data, the birthweight variable includes 44.88% missing data, the education variable includes 2.02% missing data, and the moderate or vigorous physical activity variable includes 2.43% missing data. The imputed analysis included all the respondents (n=502,489).

Reporting checklist for cross sectional study.

Based on the STROBE cross sectional guidelines.

Instructions to authors

Complete this checklist by entering the page numbers from your manuscript where readers will find each of the items listed below.

Your article may not currently address all the items on the checklist. Please modify your text to include the missing information. If you are certain that an item does not apply, please write "n/a" and provide a short explanation.

Upload your completed checklist as an extra file when you submit to a journal.

In your methods section, say that you used the STROBE cross sectional reporting guidelines, and cite them as:

von Elm E, Altman DG, Egger M, Pocock SJ, Gotsche PC, Vandenbroucke JP. The Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) Statement: guidelines for reporting observational studies.

			Page
		Reporting Item	Number
Title and abstract			
Title	#1a	Indicate the study's design with a commonly used term in the title or the abstract	1
Abstract	#1b	Provide in the abstract an informative and balanced summary	3

of what was done and what was found

Introduction

Background / [#2](#) Explain the scientific background and rationale for the 4
 rationale investigation being reported

Objectives [#3](#) State specific objectives, including any prespecified 6
 hypotheses

Methods

Study design [#4](#) Present key elements of study design early in the paper 7

Setting [#5](#) Describe the setting, locations, and relevant dates, including 7
 periods of recruitment, exposure, follow-up, and data collection

Eligibility criteria [#6a](#) Give the eligibility criteria, and the sources and methods of 7
 selection of participants.

[#7](#) Clearly define all outcomes, exposures, predictors, potential 8-9
 confounders, and effect modifiers. Give diagnostic criteria, if applicable

Data sources / [#8](#) For each variable of interest give sources of data and details of 9
 measurement methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group. Give information separately for for exposed and unexposed groups if applicable.

Bias [#9](#) Describe any efforts to address potential sources of bias 10

Study size [#10](#) Explain how the study size was arrived at 8

1	Quantitative	#11	Explain how quantitative variables were handled in the	8-9
2				
3	variables		analyses. If applicable, describe which groupings were chosen,	
4				
5			and why	
6				
7				
8				
9	Statistical	#12a	Describe all statistical methods, including those used to control	9-10
10				
11	methods		for confounding	
12				
13				
14	Statistical	#12b	Describe any methods used to examine subgroups and	10
15				
16	methods		interactions	
17				
18				
19	Statistical	#12c	Explain how missing data were addressed	10
20				
21	methods			
22				
23				
24				
25	Statistical	#12d	If applicable, describe analytical methods taking account of	8
26				
27	methods		sampling strategy	
28				
29				
30	Statistical	#12e	Describe any sensitivity analyses	10
31				
32	methods			
33				
34				
35				
36	Results			
37				
38				
39	Participants	#13a	Report numbers of individuals at each stage of study—eg	7
40				
41			numbers potentially eligible, examined for eligibility, confirmed	
42				
43			eligible, included in the study, completing follow-up, and	
44				
45			analysed. Give information separately for for exposed and	
46				
47			unexposed groups if applicable.	
48				
49				
50				
51	Participants	#13b	Give reasons for non-participation at each stage	n/a
52				
53				
54	Participants	#13c	Consider use of a flow diagram	n/a
55				
56				
57	Descriptive data	#14a	Give characteristics of study participants (eg demographic,	11
58				
59				
60				

clinical, social) and information on exposures and potential confounders. Give information separately for exposed and unexposed groups if applicable.

8	Descriptive data	#14b	Indicate number of participants with missing data for each variable of interest	11
9				
10				
11				
12				
13	Outcome data	#15	Report numbers of outcome events or summary measures. Give information separately for exposed and unexposed groups if applicable.	11
14				
15				
16				
17				
18				
19				
20				
21	Main results	#16a	Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	11-12
22				
23				
24				
25				
26				
27				
28				
29				
30				
31	Main results	#16b	Report category boundaries when continuous variables were categorized	11-12
32				
33				
34				
35				
36	Main results	#16c	If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	12
37				
38				
39				
40				
41				
42	Other analyses	#17	Report other analyses done—e.g., analyses of subgroups and interactions, and sensitivity analyses	12-13
43				
44				
45				
46				
47	Discussion			
48				
49				
50	Key results	#18	Summarise key results with reference to study objectives	13
51				
52				
53	Limitations	#19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias.	14-15
54				
55				
56				
57				
58				
59				
60				

1	Interpretation	#20	Give a cautious overall interpretation considering objectives,	14-15
2			limitations, multiplicity of analyses, results from similar studies,	
3			and other relevant evidence.	
4				
5				
6				
7				
8				
9	Generalisability	#21	Discuss the generalisability (external validity) of the study	14
10			results	
11				
12				
13				
14	Other Information			
15				
16				
17	Funding	#22	Give the source of funding and the role of the funders for the	16
18			present study and, if applicable, for the original study on which	
19			the present article is based	
20

Abstract

Objectives Exposures in utero and during infancy may impact the development of diseases later in life. They may be linked with development of frailty though the mechanism is unclear. This study aims to determine the associations between early life risk factors and development of frailty amongst middle-aged and older adults as well as potential pathways via education, for any observed association.

Design A cross-sectional study.

Settings This study used data from UK Biobank, a large population-based cohort.

Participants 502,489 individuals aged 37-73 years were included in the analysis.

Primary and secondary outcome measures Early life factors in this study included being breastfed as a baby, maternal smoking, birth weight, the presence of perinatal diseases, birth month, and birth place (in or outside the UK). We developed a frailty index comprising 49 deficits. We used generalised structural equation modelling to examine the associations between early life factors and development of frailty and whether any observed association was mediated via educational attainment.

Results A history of breastfeeding and normal birth weight were associated with a lower frailty index while maternal smoking, the occurrence of perinatal diseases and birth month with a longer day length were associated with a higher frailty index. Educational level mediated the relationship between these early life factors and frailty index.

Conclusions This study highlights that biological and social risk occurring at different stages of life are related to the variations in frailty index in later life and suggests opportunities for prevention across the life course.

Keywords early life factors, frailty, generalised structural equation model, UK Biobank

Article Summary

Strengths and limitations of this study

- Using a large cohort of British adults in middle and older age, this study was sufficiently powered to identify associations between early life factors and frailty index.
- The questionnaire on early life factors was based on self-report and is therefore subject to recall error.
- The information on the health conditions of the parents is limited, and the data on the breast feeding duration is not available.
- As the cohort is not nationally representative, the findings cannot be generalised to the general population.

Introduction

As the world's population ages, a major goal is the attainment of increased life expectancy accompanied by fewer years spent in poor health and with disability and dependency. The worldwide population of older people (65 years and above) is predicted to double from 0.7 billion (9%) in 2019 to 1.5 billion (16%) in 2050 [1]. In addition, there is evidence that the number of disability adjusted life years (DALY) among those aged 60 years and older is increasing (from 434 million in 1990 to 574 million in 2010) [2], which will increase demand for health and care services. As physical disability is an adverse outcome of frailty [3], more research in geriatrics and gerontology has focused on defining and recognising frailty among older people with the aim of determining preventive and interventional measures [4].

Frailty can be defined as a state of increased vulnerability resulting from an age-related decline in physiologic and cognitive reserves and function following stressor events [5]. The frailty index approach, developed by Rockwood et al. [6], measures frailty level as the number of deficits presents over the number of deficits considered, including symptoms, diagnoses, disabilities, and functional impairments. Frailty has become more common with the ageing of the population. A systematic review including 240 studies from 62 countries showed that 24% of people aged 50 years and older are frail as calculated using the frailty index approach [7].

Frailty has been found to be associated with adverse health outcomes including loss of mobility, disability, falls, hospitalisation, need for long-term care, and death [8-10].

Understanding the factors that are associated with frailty is thus important for developing interventions to prevent frailty and for providing directions for future public health policies.

A growing body of literature acknowledges that the first two decades of human life are critical in determining adult life trajectories. Among the early life factors, body size at birth [11-12], cigarette smoke exposure in utero [13], infants exclusively breastfed [14], birth month [15], and the presence of perinatal diseases [16] have been found to be associated with adult chronic

1
2
3 diseases. However, the study linking those factors and frailty is limited. In addition, the
4
5 evidence on the link between early life factors and occurrence of frailty have been mixed
6
7 [17,18]. The present study thus aims to determine the associations between early life factors,
8
9 including a history of being breastfed, maternal smoking, birth weight, the presence of
10
11 perinatal diseases, birth in or outside of the UK or outside the UK and birth month, and frailty
12
13 in UK adults.
14
15

16
17 Furthermore, this study contributes to the literature investigating the determinants of health
18
19 in later life by exploring the pathways of early life factors that have a lasting impact on health
20
21 in middle and old age. The pathway hypothesis posits that early life conditions are important
22
23 not only because they are directly associated with late life but also because they shape later
24
25 life experiences [19,20], including restricted educational attainment and life chances. The
26
27 most frequently hypothesised pathway between circumstances in early stages of life and adult
28
29 health is adult socioeconomic status. Pakpahan et al. showed that socioeconomic factors in
30
31 adulthood, including education, mediate the link between childhood health and
32
33 socioeconomic conditions and self-rated health among older Europeans [19]. Because
34
35 interventions that target common pathways have the potential to reduce frailty, the
36
37 identification of the pathways of early life factors leading to frailty later in life has substantial
38
39 public health relevance for the translation of life course epidemiology into practice. The
40
41 present study considers whether any observed association between early life factors and frailty
42
43 could be attributed to differences in education attainment (Figure 1).

49 **Methods**

50 **Source and Sample**

51
52 Data were drawn from the UK Biobank, a prospective cohort study of the genetic,
53
54 environmental and lifestyle causes of diseases among adults in the UK [21]. The study
55
56 involved the collection of extensive questionnaire data and biological samples from, and the
57
58
59
60

1
2
3 performance of, physical examinations of more than 500,000 respondents enrolled at 22
4 assessment sites in England, Scotland, and Wales between 2006 and 2010. Subjects who took
5 part provided written informed consent for data collection, analysis and linkage; they also
6 completed a touchscreen questionnaire, a nurse-led interview, and had their physical
7 measurements taken. The UK Biobank invited adults who were registered with a general
8 practitioner and who lived within reasonable traveling distance of the assessment centre. The
9 current study includes 502,489 individuals aged 37-73 years who had study-specific available
10 data and were not withdrawn from the study. This study was conducted as part of UK Biobank
11 Project Number 41877 and is covered by the generic ethics approval for UK Biobank studies
12 from the NHS National Research Ethics Service (16/NW/0274).

26 **Measures**

28 *Early life factors*

30 Information by questionnaire was obtained on: maternal smoking in the pre- and post-natal
31 period, history of being breastfed as a baby, birth month, birthweight, the presence of perinatal
32 diseases, and place of birth. We defined maternal smoking based on the question ‘Did your
33 mother smoke regularly around the time when you were born?’ (Data-Field 1787).
34 Respondents were categorised as having been breastfed as babies if they answered ‘yes’ to
35 the question: ‘Were you breastfed when you were a baby?’ (Data-Field 1677). We retrieved
36 information on birth month from the birth date (Data-Field 52) and treated it as the cosine of
37 the values, representing the rhythmic seasonal length of day and night. We considered this
38 might represent daylight time better than treating it as a categorical variable. This is an
39 approach which we have used in a previous study [22]. Birth months of participants born in
40 the UK and other countries in the southern hemisphere were converted to their antiphase.
41 Information on birthweight was gathered by means of self-reported birthweight in kilograms
42 (Data-Field 20022). We categorised the birth weight into low birth weight (<2,500 g), normal
43
44

1
2
3 birth weight (2,500 – 4,000 g), and high birth weight (>4,000 g). The presence of perinatal
4 diseases ('ICD10 Chapter XVI: Certain conditions originating in the perinatal period') was
5 coded as one based on self-reported medical history (Category 2416). We categorised the
6 place birth of the respondents as born in the UK or outside the UK (Data-Field 1647). Answers
7 of 'Do not know' or 'Prefer not to answer' were accepted as missing for all questions.
8
9

10 11 12 13 14 *Education*

15 The education variable represents the highest educational level completed by the respondents.
16 Qualifications were categorised as high school or less (reference) and college or university
17 degree (Data-Field 6138).
18
19

20 21 22 23 24 *Frailty index*

25 Following William et al. [23], we derived the frailty index using 49 functional, psychological,
26 and social deficits within the range of data variables in the UK Biobank (see Supplementary
27 Table 1). We coded the binary variables as 0 or 1, and for ordinal and continuous variables,
28 coding was based on distribution. The total number of deficits was summed and divided by
29 total possible deficits to create a frailty index between 0 and 1, where higher scores indicated
30 greater frailty.
31
32

33 34 35 36 37 38 39 *Covariates*

40 We included demographic and health behaviour as covariates. Demographic information
41 included age (in years; Data-Field 21003), gender (with male as the reference; Data-Field 31),
42 and ethnicity (other than Caucasian as the reference or Caucasian; Data-Field 21000). Health
43 behaviours included physical activity, alcohol intake and smoking status. Physical activity
44 was measured as the number of days per week respondents engaged in at least 10 minutes of
45 moderate or vigorous physical activity (Data-Field 884, Data-Field 904). Respondents were
46 classified as non-current smokers (reference) or current smokers (Data-Field 20116). Alcohol
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 intake status was classified as non-current (reference) or current alcohol drinking (Data-Field
4
5 20117).

8 **Statistical Analyses**

9
10 Descriptive statistics were used to summarise subject characteristics including means and
11
12 standard deviation for continuous variables and frequencies and percentages for categorical
13
14 variables. We looked at the associations between frailty index and both early life factors and
15
16 other covariates using unpaired t-tests (dichotomous variables), ANOVA (categorical
17
18 variables), and Pearson's correlation (continuous variables).

19
20 We first performed a multivariate regression model including early life factors, education, and
21
22 covariates (age, gender, ethnicity, smoking, alcohol drinking, physical activity). We further
23
24 handled missing data using multivariate imputation by chained equations (MICE) [24] (using
25
26 Stata's mi program) [25]. Twenty imputations were used.

27
28 The structural equation model (SEM) has been widely used to investigate complex
29
30 relationships between variables in epidemiological studies [26]. SEM can be used to resolve
31
32 the endogeneity problem between variables and to explore direct, indirect, and total effects
33
34 between exogenous and endogenous variables. It can jointly test a variety of hypotheses that
35
36 involve different types of complicated cause-effect relationships. However, all responses are
37
38 assumed to be continuous, even when a variable is binary or categorical. In our analysis we
39
40 include binary (education). To address this, we used a generalised structural equation model
41
42 (GSEM) to identify the link between early life factors and frailty index and the mediating
43
44 effect of education and income on that relationship. A GSEM combines generalised linear
45
46 model (GLM) estimation and SEM modelling estimation; it can accommodate binary, ordinal,
47
48 counted and categorical data [27]. Using maximum likelihood estimators, GLM estimators
49
50 are based on a density function, allowing the direct use of all types of data [28]. The analyses
51
52 were performed using MPlus version 8. We examined education as mediators of the
53
54
55
56
57
58
59
60

relationship in the GSEM model, which were controlled for age, gender, ethnicity and health behaviours (Model fit information: Chi-square=5049.35, p value=0.00; RMSEA=0.06, CFI=0.82; WRMR=13.01).

Patient and public involvement

Patients and/or the public were not involved in this study.

Results

Subjects

The study sample consisted of 502,489 respondents with an average age of 56.53 years (standard deviation [SD]=8.10 years) (Table 1). Just under half (45%) of the respondents were male, and most were Caucasian (94.59%). Around one-third of the respondents had graduated from college or university. The proportion of respondents whose mothers smoked regularly around the time of their birth was 29%. More than 72% of respondents were breastfed as babies, and 0.18% had perinatal diseases. 10% of respondents had low birth weight, while 13% of them had high birth weight. 91% of the respondents were born in the UK. Just over two-thirds of subjects reported engaging in at least 10 minutes of moderate or vigorous physical activity at least three days per week; 92% consumed alcohol and 11% were current smokers.

4 for categorical variables. The maternal smoking variable includes 13.86% missing data, the
5 breastfed as a baby variable includes 23.64% missing data, the birthweight variable includes
6 44.88% missing data, the education variable includes 2.02% missing data, and the moderate
7 or vigorous physical activity variable includes 2.43% missing data. ** Presented are the
8 means (standard deviation) of the frailty index per group. *** Bivariate analyses are unpaired
9 t-tests for binary variables, ANOVA for ordinal variables, and Pearson's correlation for
10 continuous variables.
11
12
13
14
15

16 *Early life factors, covariates and frailty index*

17
18 In bivariate analyses, compared to those whose mothers did not smoke around birth, maternal
19 pre- and post-natal smoking was associated with a significantly higher frailty index (0.146 vs
20 0.133) as was the presence of perinatal diseases (0.149 vs 0.138) and being born in the UK
21 (0.138 vs 0.137). A history of breast feeding was associated with a lower frailty index (0.134
22 vs 0.137). Low (0.149 vs 0.131) and high (0.136 vs 0.138) birthweight were associated with
23 higher frailty scores compared to normal birthweight. Shorter daylight hours at birth ($r=-0.01$)
24 were associated with lower frailty indices. As expected, the frailty index was higher among
25 women than among men and in those with lower educational attainment. The frailty index
26 was also higher in smokers, non-drinkers and those who engaged in less physical activity.
27
28
29
30
31
32
33
34
35
36
37
38

39 In regression analyses the effects of early life factors and covariates on the frailty index
40 appeared similar in terms of both magnitude and direction when using both non-imputed and
41 imputed data (see Supplementary Table 2). In these multivariate regression analyses adjusting
42 for age, gender and health behaviours, birth month with longer hours of daylight, having a
43 low and high birthweight, maternal smoking, being breastfed as baby, perinatal diseases and
44 born in the UK had positive and significant associations with frailty index.
45
46
47
48
49
50
51
52

53 *Mediation analysis*

54
55 In the GSEM model, education mediated the association between early life factors and frailty
56 index among middle-aged and older adults, supporting the pathway hypothesis. Table 2
57 presents the total, direct and indirect effects for each of the early life factors on the frailty
58
59
60

index. Maternal smoking (direct effect: coef.=0.068, z=33.40; indirect effect: coef.=0.011, z=25.54) and low birthweight (direct effect: coef.=0.041, z=20.93; indirect effect: coef.=0.003, z=9.18) and high birthweight (direct effect: coef.=0.013, z=6.34; indirect effect: coef.=0.001, z=4.09) directly and indirectly affected the frailty index compared to normal birthweight. The direct and indirect effects of being breastfed as a baby on having a lower frailty index were -0.022 (z=-10.36) and -0.009 (z=-22.91). Perinatal diseases had significant direct effect on higher frailty index (coef.=0.007, z=3.83), but it had no indirect effect on the frailty index (coef.=0.000, z=0.27). Being born in the UK, differently, had a significant indirect effect on higher frailty index (coef.=0.016, z=31.24), but it had no direct effect on the frailty index (coef.=0.002, z=0.74). Birth months with a short daylength were directly (coef.=-0.006, z=-2.91) and indirectly (coef.=-0.001, p-value=-2.35) associated with lower frailty scores.

Table 2. Total, direct, and indirect effects of early life factors on frailty index

	Total effects	Direct effects	Indirect effects
Breastfed as a baby	-0.031 (0.002)†	-0.022 (0.002)†	-0.009 (0.000)†
Maternal smoking around birth	0.079 (0.002)†	0.068 (0.002)†	0.011 (0.000)†
Low birth weight	0.045 (0.002)†	0.041 (0.002)†	0.003 (0.000)†
High birth weight	0.015 (0.002)†	0.013 (0.002)†	0.001 (0.000)†
Birth month (cos)	-0.007 (0.002)*	-0.006 (0.002)*	-0.001 (0.000)*
Perinatal diseases	0.007 (0.002)†	0.007 (0.002)†	0.000 (0.000)
Born in the UK	0.018 (0.002)†	0.002 (0.002)	0.016 (0.001)†

Education mediated the links between early life factors and frailty index (Figure 2). Participants born in the UK had a lower probability of completing higher education (coef.=-0.130, z=-44.65). Having been breastfed as a baby (coef.=0.076, z=26.87) was associated with higher educational attainment, while maternal smoking was associated with lower educational attainment (coef.=-0.087, z=-31.41). Both low (coef.=-0.027, z=-9.39) and high birthweight (coef.=-0.011, z=-4.11) was related to lower education attainment compared to normal

1
2
3 birthweight. Birth months with short daylight was related to higher education with the lowest
4 effect size (coef.=0.006, z=2.35). Higher education was also associated with a lower frailty
5 index (coef.=-0.123, z=-44.30). Amongst covariates with greater effect sizes, older age
6 (coef.=0.178, z=83.25), lower activity levels (coef.=-0.088, z=-45.61) and smoking
7 (coef.=0.106, z=56.36) were associated with a higher frailty index. Drinking alcohol is related
8 to lower frailty index (coef.=-0.093; z=-51.63).

16 **Discussions**

17
18 Using data from UK Biobank we found that a history of breastfeeding was associated with a
19 lower frailty index, while maternal smoking, having low or high birth weight, perinatal
20 diseases and birth month with longer day length were associated with a higher frailty index.
21
22 This study provides the first evidence that educational attainment level mediates the
23 association between early life factors and frailty index.
24
25

26
27 Early life factors have previously been linked with higher frailty and chronic disease risk later
28 in life [29,30]. Our findings highlight the importance of early life factors in determining frailty
29 in middle age and older individuals. Maternal smoking was directly associated with higher
30 frailty compared to those who were not exposed to maternal smoking. Evidence has suggested
31 that cigarette smoke exposure in utero is linked to the development of chronic diseases later
32 in life, including type 2 diabetes, obesity, certain cancers and respiratory disorders [13]. We
33 also showed that this association was mediated by educational attainment. This is in line with
34 a previous study which reported lower academic achievements of adolescents whose mothers
35 smoked during pregnancy [31]. Maternal smoking during pregnancy was also found to be
36 correlated with the children's cognitive function [32].

53
54 There is some evidence of a link between early life factors and occurrence of frailty. In a
55 recent study in Finland, greater weight, length and BMI at birth were associated with a lower
56 risk of frailty later in life [17]. In our study, having low or high birth weight were associated
57
58
59
60

1
2
3 with higher frailty index compared to having a normal birthweight, both directly and
4 indirectly through education. Bleker and colleagues found that prenatal undernutrition was
5 not associated with frailty but was associated with poorer health in old age, including slower
6 gait speed and lower physical functioning which are components of the frailty phenotype, and
7 the findings remained significant after inclusion of an extensive set of control variables
8 including adult socioeconomic status [18]. Low birth weight is associated with increased risk
9 of age-related diseases in prior review, and insulin-like growth factor (IGF-1) is the key driver
10 of this process [33]. High birth weight may be the results of maternal obesity [34] and a study
11 in Finland found that being born large for gestational age at term was associated with thicker
12 carotid intima medial as the marker of subclinical atherosclerosis [35]. We also found that
13 individuals who reported that they were breastfed have a lower frailty score. Infants
14 exclusively breastfed have been found to have a lower risk of obesity, type 2 diabetes and
15 high blood pressure in adulthood [14].

16
17 Birth month is associated with lower frailty index scores with a limited effect size in our study.
18
19 In a large study in the US with 1,749,400 individuals showed that spring summer-born
20 individuals have a relatively higher cardiovascular disease risk than autumn-winter born
21 individuals and these seasons coincide with lower life expectancy [36]. This study showed
22 that not only cardiovascular diseases, but several chronic diseases were associated with season
23 of birth, having a different seasonal pattern. The underlying mechanisms may differ for each
24 of these associations, such as sensitization to allergens or vitamin D deficiency [36]. Another
25 possible mechanism is that differential light exposure during perinatal period influences
26 development of the biological clock, in turn influencing later-life circadian rhythms and the
27 sleep system, which are essential for health [37]. In European countries, it was shown that
28 spring/summer born participants compared to autumn had higher frailty scores but this effect
29 seemed independent of education [38]. However, we found an indirect effect of season of

2
3 birth through education. The indirect relationship of season of birth and frailty may be due to
4 social factors such as the UK September date cut-off for starting education, which is in line
5 with our findings showing an association between winter-born individuals and higher
6 educational attainment [39,40].
7
8
9

10
11
12 Our results further suggest that having a perinatal disease was associated directly with higher
13 frailty index scores. This finding is in keeping with that new-borns' perinatal complications
14 are related to accelerated ageing at midlife [16]. Being born in the UK affected the frailty
15 index indirectly through education, but not directly. Respondents who were not born in the
16 UK were likely to have higher education attainment, which may enable better maintenance of
17 health during older ages. However, we should note that our sample in this analysis may not
18 be representative of the general population, and that participants were categorised as being
19 born outside the UK without taking into account the country of origin and their socioeconomic
20 background. In our analysis, we observed that education levels mediate the link between the
21 other early life factors and the frailty index. Early life factors have a significant relationship
22 with educational attainment, and higher education attainment is linked to a lower frailty index.
23 This result is broadly in keeping with a prior study in Sweden which found that the
24 associations between childhood conditions and various old age health indicators
25 (musculoskeletal disorders, cardiovascular disease, self-rated health and impaired mobility)
26 are mediated by education [41]. Prior research on the biological and psychological pathways
27 linked childhood health and socioeconomic conditions to self-reported health status among
28 older adults in 15 European countries [19]. Prior studies have shown that the life-course
29 trajectories of socioeconomic attainment could be altered by physical and social conditions
30 [42], and both childhood and adult conditions may impact health decades later [43]. Our
31 findings have potential implications for policies aiming at preventing frailty among older
32 adults. Subsequent circumstances mediate the impact of early life factors on frailty later in

1
2
3 life, and our study suggests that interventions such as improving education in midlife may
4
5 mitigate early life disadvantages.
6

7
8 Our findings are based on a large and well characterised cohort. There are, however, a number
9
10 of limitations to be consider in interpreting the results. First, information concerning early life
11
12 factors in this study was based on self-report and is therefore subject to recall error. The likely
13
14 effect of such error would be to underestimate the relationship between these factors and the
15
16 frailty index. Second, we have limited access to the health conditions of the parents. A broad
17
18 range of conditions which are comprised in the frailty index bear a hereditary risk, thus taking
19
20 into account the health conditions of the parents is important in assessing the independent
21
22 associations with frailty. Future studies may include the health conditions of the parents as
23
24 the covariates. Third, the information on breast feeding duration is unavailable. Breast feeding
25
26 for weeks rather than months may confer different outcomes. A dose response relationship
27
28 thus cannot be assessed. Finally, these data were based on a sample of predominantly
29
30 Caucasian men and women and should be extrapolated beyond this group with caution [44].
31
32
33

34
35 In conclusion, this study indicates an association between early life factors and frailty later in
36
37 life. Early life conditions are important as the start of a mediated, incremental process during
38
39 the life course. A comprehensive understanding of the determinants of frailty among middle-
40
41 aged and older adults requires attention to exposures throughout the entire life course, with a
42
43 special focus on the in utero and infancy stages and the chains of associated socioeconomic
44
45 conditions that that connect over the life course. Applying a life course perspective to health
46
47 in adulthood and old age should have implications for public health interventions, social
48
49 policy, and further research. Early life is not the only period for any potential successful
50
51 intervention; as our findings show, early life disadvantages may be offset by education and
52
53 material wealth. Interventions throughout the life course, and especially during early life,
54
55 could substantially reduce the health burden later in life.

Contributorship statement

A.D and A.M performed the data analysis. A.D and A.M drafted the manuscript. N.P, T.W.O, M.M.C., A.P. and were involved in planning and supervised the work. All authors discussed the results and commented on the manuscript.

Competing interest

All authors declare no conflicts of interest.

Funding

Altug Didikoglu was supported by a grant from the Republic of Turkey Ministry of National Education.

Data sharing statement

Data are available in a public, open access repository. Other researchers can apply for UK Biobank data to answer specific research questions.

Ethics Approval

This study was conducted as part of UK Biobank Project Number 41877 and is covered by the generic ethics approval for UK Biobank studies from the NHS National Research Ethics Service (16/NW/0274).

Frailty index

Supplementary Material: Pathways linking early life factors and frailty among middle-aged and older adults in England: Findings from UK Biobank

Supplementary Table 1. Variables included in the UK Biobank frailty indices

Item	Variable	Definition	Coding
	Sensory		
1	Glaucoma	Self-report of physician-diagnosed glaucoma	0=no; 1=yes
2	Cataracts	Self-report of physician-diagnosed glaucoma	0=no; 1=yes
3	Hearing difficulty	Self-report experiencing hearing difficulty	0=no; 1=yes/completely deaf
	Cranial		
4	Migraine	Self-report of physician-diagnosed migraine	0=no; 1=yes
5	Dental problems	Self-report of physician-diagnosed dental problems, i.e., ulcers, painful gums, bleeding gums, loose teeth, toothache, dentures	0=none; 1=any
	Mental well-being		
6	Self-rated health	Self-rated health in 4 Likert scale	0=excellent; 0.25=good; 0.5=fair; 1=poor
7	Fatigue	Self-report of frequency of tiredness / lethargy in last two weeks	0=not at all; 0.25=several days; 0.5=more than half; 1=nearly every day
8	Sleep	Self-report experiencing of sleeplessness/ insomnia	0=never/rarely; 0.5=sometimes; 1=usually
9	Depressed feelings	Self-report of frequency having depressed feeling in last two weeks	0=not at all; 0.5=several days; 0.75=more than half; 1=nearly every day
10	Self-described nervous personality	Self-report of having nervous personality	0=no; 1=yes
11	Severe anxiety/ panic attacks	Self-report of physician-diagnosed severe anxiety/panic attacks	0=no; 1=yes
12	Common to feel loneliness	Self-report of feeling lonely commonly	0=no; 1=yes
13	Sense of misery (ever/never)	Self-report of ever having sense of misery	0=no; 1=yes
	Infirmity		
14	Infirmity	Self-report of having long-standing illness or disability	0=no; 1=yes
15	Falls in last year	Self-report of experiencing falls last year	0=no falls; 0.5=one fall; 1=more than one fall
16	Fractures/broken bones in last five years	Self-report of experiencing fractures/broken bones in last five years	0=no; 1=yes
	Cardiometabolic		
17	Diabetes	Self-report of physician-diagnosed diabetes	0=no; 1=yes
18	Myocardial infarction	Self-report of physician-diagnosed myocardial infarction	0=no; 1=yes
19	Angina	Self-report of physician-diagnosed angina	0=no; 1=yes
20	Stroke	Self-report of physician-diagnosed stroke	0=no; 1=yes
21	High blood pressure	Self-report of physician-diagnosed high blood pressure	0=no; 1=yes
22	Hypothyroidism	Self-report of physician-diagnosed hypothyroidism	0=no; 1=yes
23	Deep-vein thrombosis	Self-report of physician-diagnosed deep-vein thrombosis	0=no; 1=yes
24	High cholesterol	Self-report of physician-diagnosed high cholesterol	0=no; 1=yes

	Respiratory		
25	Breathing	Self-report of having wheeze in last year	0=no; 1=yes
26	Pneumonia	Self-report of physician-diagnosed pneumonia	0=no; 1=yes
27	Chronic bronchitis/emphysema	Self-report of physician-diagnosed chronic bronchitis/emphysema	0=no; 1=yes
28	Asthma	Self-report of physician-diagnosed asthma	0=no; 1=yes
	Musculoskeletal		
29	Rheumatoid arthritis	Self-report of physician-diagnosed rheumatoid arthritis	0=no; 1=yes
30	Osteoarthritis	Self-report of physician-diagnosed osteoarthritis	0=no; 1=yes
31	Gout	Self-report of physician-diagnosed gout	0=no; 1=yes
32	Osteoporosis	Self-report of physician-diagnosed osteoporosis	0=no; 1=yes
	Immunological		
33	Hay fever, allergic rhinitis or eczema	Self-report of physician-diagnosed hay fever, allergic rhinitis or eczema	0=no; 1=yes
34	Psoriasis	Self-report of physician-diagnosed psoriasis	0=no; 1=yes
	Cancer		
35	Any cancer diagnosis	Self-report of physician-diagnosed any cancer	0=no; 1=yes
36	Multiple cancers diagnosed (number reported)	Self-report of physician-diagnosed multiple cancer	0=no cancer or single cancer; 1=multiple cancer
	Pain		
37	Chest pain	Self-report of ever experiencing chest pain	0=no; 1=yes
38	Head and/or neck pain	Self-report of ever experiencing head and/or neck pain	0=no; 1=yes
39	Back pain	Self-report of ever experiencing back pain	0=no; 1=yes
40	Stomach/abdominal pain	Self-report of ever experiencing stomach/abdominal pain	0=no; 1=yes
41	Hip pain	Self-report of ever experiencing hip pain	0=no; 1=yes
42	Knee pain	Self-report of ever experiencing knee pain	0=no; 1=yes
43	Whole-body pain	Self-report of ever experiencing whole-body pain	0=no; 1=yes
44	Facial pain	Self-report of ever experiencing facial pain	0=no; 1=yes
45	Sciatica	Self-report of physician-diagnosed sciatica	0=no; 1=yes
	Gastrointestinal		
46	Gastric reflux	Self-report of physician-diagnosed gastric reflux	0=no; 1=yes
47	Hiatus hernia	Self-report of physician-diagnosed hiatus hernia	0=no; 1=yes
48	Gall stones	Self-report of physician-diagnosed gall stones	0=no; 1=yes
49	Diverticulitis	Self-report of physician-diagnosed diverticulitis	0=no; 1=yes

Notes: Deficit points are summed for each individual, and divided by the total number of deficits, to produce a frailty index with a range from 0 to 1.

Supplementary Table 2. Regression models predicting frailty index

	Non-imputed data¹	Imputed data¹
	(n=190,575)	(n=502,489)
Breastfed as a baby	-0.0042 (-0.0048,-0.0035)†	-0.0045 (-0.0051,-0.0038)†
Maternal smoking	0.0118 (0.0111,0.0125)†	0.0122 (0.0116,0.0128)†
Low birthweight	0.0108 (0.0097,0.0118)†	0.0114 (0.0105,0.0122)†
High birthweight	0.0030 (0.0021,0.0039)†	0.0036 (0.0028,0.0044)†
Perinatal diseases	0.0117 (0.0049,0.0185)*	0.0107 (0.0046,0.0167)*
Birth month (cos)	-0.0006 (-0.0011,-0.000)*	-0.0006 (-0.0010,-0.0002)*
Born in the UK	0.0024 (0.0011,0.0037)†	0.0018 (0.0006,0.0030)*
Education	-0.0140 (-0.0147,-0.0134)†	-0.0144 (-0.0150,-0.0139)†
Age (years)	0.0015 (0.0015,0.0015)†	0.0015 (0.0015,0.0016)†
Male	-0.0084 (-0.0090,-0.0078)†	-0.0084 (-0.0090,-0.0079)†
Caucasian ethnicity	-0.0069 (-0.0088,-0.0050)†	-0.0068 (-0.0085,-0.0051)†
Smoking	0.0244 (0.0234,0.0254)†	0.0248 (0.0239,0.0257)†
Alcohol drinking	-0.0260 (-0.0272,-0.0248)†	-0.0268 (-0.0279,-0.0258)†
Physical activity	-0.0065 (-0.0068,-0.0062)†	-0.0069 (-0.0072,-0.0067)†
Intercept	0.0976 (0.0947,0.1005)†	0.0998 (0.0972,0.1024)†

Note: ¹ presented are coefficients (95% confidence intervals); *Significant at 0.05; † Significant at 0.0001. Non-imputed analysis was based on 214,104 respondents with complete information on all variables. The maternal smoking variable includes 13.86% missing data, the breastfed as a baby variable includes 23.64% missing data, the birthweight variable includes 44.88% missing data, the education variable includes 2.02% missing data, and the moderate or vigorous physical activity variable includes 2.43% missing data. The imputed analysis included all the respondents (n=502,489).

Reporting checklist for cross sectional study.

Based on the STROBE cross sectional guidelines.

Instructions to authors

Complete this checklist by entering the page numbers from your manuscript where readers will find each of the items listed below.

Your article may not currently address all the items on the checklist. Please modify your text to include the missing information. If you are certain that an item does not apply, please write "n/a" and provide a short explanation.

Upload your completed checklist as an extra file when you submit to a journal.

In your methods section, say that you used the STROBE cross sectional reporting guidelines, and cite them as:

von Elm E, Altman DG, Egger M, Pocock SJ, Gotsche PC, Vandenbroucke JP. The Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) Statement: guidelines for reporting observational studies.

			Page
		Reporting Item	Number
Title and abstract			
Title	#1a	Indicate the study's design with a commonly used term in the title or the abstract	1
Abstract	#1b	Provide in the abstract an informative and balanced summary	3

of what was done and what was found

Introduction

Background / [#2](#) Explain the scientific background and rationale for the 4
 rationale investigation being reported

Objectives [#3](#) State specific objectives, including any prespecified 6
 hypotheses

Methods

Study design [#4](#) Present key elements of study design early in the paper 7

Setting [#5](#) Describe the setting, locations, and relevant dates, including 7
 periods of recruitment, exposure, follow-up, and data collection

Eligibility criteria [#6a](#) Give the eligibility criteria, and the sources and methods of 7
 selection of participants.

[#7](#) Clearly define all outcomes, exposures, predictors, potential 8-9
 confounders, and effect modifiers. Give diagnostic criteria, if applicable

Data sources / [#8](#) For each variable of interest give sources of data and details of 9
 measurement methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group. Give information separately for for exposed and unexposed groups if applicable.

Bias [#9](#) Describe any efforts to address potential sources of bias 10

Study size [#10](#) Explain how the study size was arrived at 8

1	Quantitative	#11	Explain how quantitative variables were handled in the	8-9
2				
3	variables		analyses. If applicable, describe which groupings were chosen,	
4				
5			and why	
6				
7				
8				
9	Statistical	#12a	Describe all statistical methods, including those used to control	9-10
10				
11	methods		for confounding	
12				
13				
14	Statistical	#12b	Describe any methods used to examine subgroups and	10
15				
16	methods		interactions	
17				
18				
19	Statistical	#12c	Explain how missing data were addressed	10
20				
21	methods			
22				
23				
24				
25	Statistical	#12d	If applicable, describe analytical methods taking account of	8
26				
27	methods		sampling strategy	
28				
29				
30	Statistical	#12e	Describe any sensitivity analyses	10
31				
32	methods			
33				
34				
35				
36	Results			
37				
38				
39	Participants	#13a	Report numbers of individuals at each stage of study—eg	7
40				
41			numbers potentially eligible, examined for eligibility, confirmed	
42				
43			eligible, included in the study, completing follow-up, and	
44				
45			analysed. Give information separately for for exposed and	
46				
47			unexposed groups if applicable.	
48				
49				
50				
51	Participants	#13b	Give reasons for non-participation at each stage	n/a
52				
53				
54	Participants	#13c	Consider use of a flow diagram	n/a
55				
56				
57	Descriptive data	#14a	Give characteristics of study participants (eg demographic,	11
58				
59				
60				

clinical, social) and information on exposures and potential confounders. Give information separately for exposed and unexposed groups if applicable.

8	Descriptive data	#14b	Indicate number of participants with missing data for each variable of interest	11
9				
10				
11				
12				
13	Outcome data	#15	Report numbers of outcome events or summary measures. Give information separately for exposed and unexposed groups if applicable.	11
14				
15				
16				
17				
18				
19				
20				
21	Main results	#16a	Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	11-12
22				
23				
24				
25				
26				
27				
28				
29				
30				
31	Main results	#16b	Report category boundaries when continuous variables were categorized	11-12
32				
33				
34				
35				
36	Main results	#16c	If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	12
37				
38				
39				
40				
41				
42	Other analyses	#17	Report other analyses done—e.g., analyses of subgroups and interactions, and sensitivity analyses	12-13
43				
44				
45				
46				
47	Discussion			
48				
49				
50	Key results	#18	Summarise key results with reference to study objectives	13
51				
52				
53	Limitations	#19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias.	14-15
54				
55				
56				
57				
58				
59				
60				

1	Interpretation	#20	Give a cautious overall interpretation considering objectives,	14-15
2			limitations, multiplicity of analyses, results from similar studies,	
3			and other relevant evidence.	
4				
5				
6				
7				
8				
9	Generalisability	#21	Discuss the generalisability (external validity) of the study	14
10			results	
11				
12				
13				
14	Other Information			
15				
16				
17	Funding	#22	Give the source of funding and the role of the funders for the	16
18			present study and, if applicable, for the original study on which	
19			the present article is based	
20				
21				
22				
23				
24
