Abstract

Here we report that PSD-95, a postsynaptic density scaffolding protein classically conceptualized as being essential for the regulation of ionotropic glutamatergic signaling at the post-synaptic membrane, plays an unanticipated and essential role in mediating the actions of hallucinogens and atypical antipsychotic drugs at $5\text{-}HT_{2A}$ and $5\text{-}HT_{2C}$ serotonergic G protein-coupled receptors (GPCRs). We show that PSD-95 is crucial for normal $5\text{-}HT_{2A}$ and $5\text{-}HT_{2C}$ expression *in vivo*, and that PSD-95 maintains normal receptor expression by promoting apical dendritic targeting and stabilizing receptor turnover *in vivo*. Significantly, $5\text{-}HT_{2A}$ and $5\text{-}HT_{2C}$-mediated downstream signaling is impaired in PSD-95^{null} mice, and the $5\text{-}HT_{2A}$-mediated head twitch response is abnormal. Furthermore, the ability of $5\text{-}HT_{2A}$ inverse agonists to normalize behavioral changes induced by glutamate receptor antagonists is abolished in the absence of PSD-95 *in vivo*. These results demonstrate that PSD-95, in addition to the well known role it plays in scaffolding macromolecular glutamatergic signaling complexes, profoundly modulates metabotropic $5\text{-}HT_{2A}$ and $5\text{-}HT_{2C}$ receptor function.

Introduction

Known hallucinogens include LSD-like hallucinogens such as mescaline, LSD, psilocin, and DMT (Nichols, 2004), and non-LSD-like hallucinogens such as salvinorin A (Roth et al., 2002). $5\text{-}HT_{2A}$ serotonin receptors, which represent the main site of action of the LSD-type hallucinogens (Glennon et al., 1984), are most heavily expressed in the apical dendrites and

soma of pyramidal neurons in cortical layers II, III, V, and VI (Willins et al., 1997), (Jakab and Goldman-Rakic, 1998), and knockout and tissue-specific rescue studies indicate that cortical 5-HT_{2A} receptors are the main site of action of hallucinogens (Gonzalez-Maeso et al., 2007). Moreover, the 5-HT_{2A} inverse agonist property of atypical antipsychotic drugs is thought to be an essential feature of their therapeutic actions (Meltzer et al., 1989), (Roth et al., 2004a), (Gray and Roth, 2007).

The closely related 5-HT_{2C} serotonin receptors are located primarily in choroid plexus, striatum, and hippocampus (Molineaux et al., 1989), (Clemett et al., 2000), (Lopez-Gimenez et al., 2002). 5-HT_{2C} receptors are unique among GPCRs in that they are post-transcriptionally edited (Burns et al., 1997), a process which affects constitutive activity (Niswender et al., 1999) and the efficiency of G-protein coupling in a functionally selective manner (Price and Sanders-Bush, 2000), (Berg et al., 2001), (Urban et al., 2007). A number of drugs targeting 5-HT_{2C} receptors have been shown to be efficacious in animal models of schizophrenia, OCD, depression, and obesity (Gray and Roth, 2007), (Dunlop et al., 2005), (Marquis et al., 2007), (Dunlop et al., 2006), (Sard et al., 2005).

Previous studies by our lab and others have demonstrated that the 5-HT_{2A} and 5-HT_{2C} receptors, which are essential for the actions of atypical antipsychotic drugs and LSD-like hallucinogens (Roth et al., 2004a), (Gonzalez-Maeso et al., 2007), (Berger et al, 2009), can interact *in vitro* via a canonical Type I PDZ binding motif (Becamel et al., 2002), (Xia et al., 2003a), (Becamel et al., 2004) with postsynaptic density protein of 95 kDa (PSD-95), a PDZ domain-containing scaffolding protein (Nicoll et al., 2006), (Chen et al., 2000), (Kim et al., 2006) that is an essential regulator of ionotropic glutamatergic neuronal signaling (Migaud et al., 1998), (Ehrlich and Malinow, 2004), (Sheng and Kim, 2002), (Schluter et al., 2006), (Xu et al., 2008). These *in vitro* data suggest that PSD-95 could play a critical role in regulating 5-HT_{2A} and 5-HT_{2C} receptors in neurons *in vivo*, tethering these receptors to the plasma membrane and regulating their trafficking and function. In this paper we show that genetic deletion of PSD-95 leads to profound alterations in 5-HT_{2A} and 5-HT_{2C} receptor targeting, expression, and signaling. We also show that these 5-HT receptor-PSD-95 interactions are essential for the normal function of the 5-HT_{2A} and 5-HT_{2C} receptors, including their abilities to mediate hallucinogen and atypical antipsychotic drug actions *in vivo*. Our findings provide new insights into the precise subcellular site(s) of action of hallucinogens and atypical antipsychotic drugs, as well as implicate PSD-95 as an important regulator of metabotropic 5-HT_{2A} and 5-HT_{2C} receptor function.

Materials and Methods

Mice

A detailed description of how the PSD-95[null] mice were generated will be reported in a future publication (S.G.G.). Briefly, PSD-95[null] mice were made by deleting the guanylate kinase (GK) domain of the protein. This results in an almost complete absence of PSD-95 mRNA (approximately 5.7% of WT levels, as assessed by gene microarray). Previous studies with these mice using two different antibodies raised against epitopes N-terminal to the GK domain of PSD-95 detected no PSD-95 protein whatsoever in the mutant mice (Yao et al., 2004). Our immunochemical studies confirm these findings (Figure 1A). All experiments were approved by the Institutional Animal Care and Use Committee at Case Western Reserve University or the University of North Carolina, Chapel Hill. Mice were housed under standard conditions – 12 hour light/dark cycle and food and water ad libitum.

Immunochemistry

The following antibodies and dilutions were used: mouse anti-5-HT$_{2A}$ (Pharmingen/BD Biosciences) - 1:500 (sections), 1:1000 (neurons); mouse anti-PSD-95 (Upstate Biotechnology) – 1:1000; mouse anti-5-HT$_{2C}$ D-12 (Santa Cruz Biotechnology) – 1:500; rabbit anti-MAP2 (Chemicon) – 1:1000; rabbit anti-GFP A11122 (Invitrogen) – 1:1000; rabbit anti-c-fos PC38 (Calbiochem) – 1:1000; Alexa Fluor 488 goat anti-mouse or goat anti-rabbit, and Alexa Fluor 594 goat anti-mouse or goat anti-rabbit (Invitrogen) – 1:200. For immunochemistry on brain tissue sections, PSD-95^{wildtype} and PSD-95^{null} mice were perfused with 4% paraformaldehyde in 1X PBS and their brains harvested and placed overnight in 4% paraformaldehyde in 1X PBS at 4°C. Over the next night brains were placed in 30% sucrose in 1X PBS until they sank, then frozen on dry ice and stored at −80°C. Sections were either free-floating in 1X PBS (one or two sections per well in a 24 well plate) or thaw-mounted onto coated microscope slides, and they were then permeabilized with .3% Triton in 1X PBS for 15–20 minutes. For immunochemistry on cultured cortical neurons, DIV 4 neurons were washed twice with 1X PBS, fixed in 4% paraformaldehyde in 1X PBS for 30 minutes, then washed twice more with 1X PBS before permeabilizing. Blocking was performed using 5% milk in 1X PBS for 1–2 hours. Primary antibodies were incubated in 5% milk in 1X PBS at room temperature for 2 hours or overnight at 4°C while shaking. Sections were then washed 3 times in 1X PBS (10 minutes for each wash). Secondary antibodies were incubated in 5% milk in 1X PBS at room temperature for 1 hour in the dark, while shaking. Sections were washed 3 times in 1X PBS (10 minutes for each wash). Free-floating sections and neuronal cover slips were transferred to a microscope slide and mounted for fluorescence microscopic visualization.

Saturation radioligand binding

For saturation binding assays, brain regions were microdissected and frozen on dry ice, then stored at −80°C. A Tissue Tearor™ (BioSpec Products) was used to homogenize tissue (10 seconds, 15,000 rpm) in 2 ml of standard binding buffer (SBB - 50 mM TrisHCl, pH 7.4; 10 mM MgCl$_2$; .1 mM EDTA). Homogenized tissue was spun for 10 min at $26,000 \times g$ (4°C), and the SBB removed. The pellet was resuspended in 1 ml of SBB and transferred to a 1.7 ml eppendorf tube, then spun at top speed in a microcentrifuge for 5 minutes at 4°C. The SBB was removed and the pellet was either used immediately for binding or stored at −80°C until use. Saturation binding assays were performed with the homogenized brain tissue and [^{3}H]-ketanserin (5-HT$_{2A}$; cortex); [^{3}H]-mesulergine + 100 nM spiperone (5-HT$_{2C}$, hippocampus); or [^{3}H]-WAY100635 (5-HT$_{1A}$, cortex, hippocampus), then incubated in SBB for 1.5 hours. The following [^{3}H] concentrations were used: 8 nM, 6 nM, 4 nM, 2 nM, 1.5 nM, 1.0 nM, .5 nM, .25 nM (5-HT$_{2A}$ and 5-HT$_{2C}$) or 2 nM, 1.2 nM, .8 nM, .4 nM, .2 nM, .1 nM, .05 nM, .025 nM (5-HT$_{1A}$), all in duplicate for total and nonspecific (4 reactions at each concentration for each brain sample in which receptor was measured). Nonspecific was determined by incubating the reactions with 8 μM ritanserin (5-HT$_{2A}$ and 5-HT$_{2C}$) or 10 μM 5-HT (5-HT$_{1A}$). For 5-HT$_{2C}$ measurements 3 samples were pooled for each assay. Bradford protein assays were performed in order to normalize B$_{max}$ determinations to the amount of protein in each assay. Reactions were harvested by vacuum filtration through glass filters (3X ice cold 50 mM Tris, pH 7.4; pH 6.9 at room temperature) and counted by liquid scintillation using a Perkin-Elmer Tri-Carb 2800TR. Microsoft Excel and Graphpad Prism were used for all data analysis.

EEDQ

EEDQ (dissolve EEDQ in 100% ethanol, than dilute 1:3 in saline) was injected i.p. at a dose of 10 mg/kg. Mice were sacrificed at 1, 2, 3, 5, 7, and 13 days post-EEDQ treatment, and the 5-HT$_{2A}$ B$_{max}$ was measured by saturation binding. Receptor production was assumed to be a

zero-order process and receptor trafficking a 1st-order process (Pinto and Battaglia, 1994). Thus, the equation derived to model receptor recovery was:

$$[B_{max}]_t = [B_{max}]_{ss}(1 - e^{-kt})$$

where $[B_{max}]_t$ is the amount of receptor at time t, $[B_{max}]_{ss}$ is the steady state B_{max} after the receptors have recovered, k is the rate constant for receptor turnover (inverse days, or d^{-1}), and t is the time at which $[B_{max}]_t$ was measured in days. This model was fit by non-linear least squares regression to a plot of the average B_{max} value at each time point.

Quantitative RT-PCR

Trizol (Invitrogen) was used to extract RNA from microdissected cortical tissue. 10 μg of RNA was treated with DNAse (DNA-free, Ambion), and 2 μg of the DNase-treated RNA was added to a reverse transcription reaction which was performed using the Superscript™ III RNase H Reverse Transcriptase kit (Invitrogen) with Oligo-(dT)$_{12-18}$ primers (Invitrogen). IQ SYBR Green Supermix (BioRAD) was used in a 7300 RT PCR System (Applied Biosystems) for quantitation. All steps were performed according to manufacturer's instructions.

Microarray experiment

RNA was extracted from microdissected cortical tissue using Trizol (Invitrogen). The gene chip assay was performed by the Gene Expression and Genotyping Core Facility at the Case Comprehensive Cancer Center using the Affymetrix Genechip® Mouse Genome 430 2.0 Array. Data was analyzed using the Affymetrix Genechip Operating Software, version 1.4.0.036.

5-HT$_{2C}$ mRNA editing

Microdissected hippocampal tissue was pooled by genotype and used to generate cDNA as described above. The following primers were used to generate a PCR fragment (containing the edited site) that was 327 base pairs in length that was then inserted into the BamHI/EcoRI sites of pcDNA3: FORWARD PRIMER: 5′ AAA GGATCC TGT GCT ATT TTC AAC TGC GTC CAT CAT G 3′; REVERSE PRIMER: 5′ AAA GAATTC CGG CGT AGG ACG TAG ATC GTTAAG 3′ (Du et al., 2006). Each bacterial colony resulting from transformation of the ligation product represents a transcript. Clones were miniprepped and sequenced to determine the extent of editing for each transcript.

Cortical neuronal cultures

Cortical neurons were prepared from P0.5 mouse pups as described previously by others (Ahlemeyer and Baumgart-Vogt, 2005). Briefly, cortex was microdissected in Mg^{2+} Hank's buffered salt solution (HBSS) under a dissecting microscope and incubated at 37°C for 20 minutes in neurobasal medium containing .1% papain and .02% BSA. The supernatant was removed and the tissue was then mechanically triturated in neurobasal medium. The supernatant was transferred to a new sterile eppendorf, leaving the aggregates, and spun down at $200 \times g$ for 10 minutes. The supernatant was discarded and the pellet resuspended in pre-equilibrated (to 37°C and 5% CO_2) neurobasal medium containing B27 supplement, antibiotics, and .5 mM glutamine, and plated on cover slips coated with low molecular weight poly-L-lysine. Immunochemical experiments were performed at 4–5 DIV.

Lentiviral preparation

PSD-95 was cloned into FUGW (Lois et al., 2002) by ligating a BclI-digested PSD-95 PCR fragment into the BamHI site 5′ to the GFP (FORWARD PRIMER: 5′ – AAA TGA TCA ATG

GAC TGT CTC TGT ATA GTG ACA ACC – 3′; REVERSE PRIMER: 5′ – AAA TGA TCA GAG TCT CTC TCG GGC TGG GAC CCA – 3′). Site-directed mutagenesis was performed to mutate away the stop site that results from the BclI-BamHI ligation at the 3′ end of PSD-95 and shift the reading frame so that PSD-95 is in frame with GFP (SENSE PRIMER: 5′ – GCC CGA GAG AGA CTC TTA TTT CCC CCG GGG GTA CCG GT – 3′; ANTISENSE PRIMER: 5′ – ACC GGT ACC CCC GGG GGA AAT AAG AGT CTC TCT CGG GC – 3′). Fugene6 (50 μL Fugene6, 10 μg total DNA per 10 cm plate) was used to co-transfect HEK293T cells with 3 plasmids (FUGW/Δ8.9 HIV-1/VSVG) in a ratio of 3.3/2.5/1. Lentivirus-containing media was collected 48 hours later and filtered through a .45 μM filter to remove cellular debris. Lentivirus was aliquoted and frozen at −80°C until use. Cortical neurons were infected with 20–50 μL GFP or PSD-95 GFP lentivirus at 2 DIV. Immunochemistry was performed at 5 DIV.

MK-212-induced c-fos in hippocampus

Mice were injected i.p. with 5 mg/kg MK-212 in .9% sterile NaCl or vehicle. 45 minutes later they were perfused with 4% paraformaldehyde. Frozen sections (Bregma −1.34 mm to Bregma −2.7 mm) were thaw mounted onto frosted slides and then used for immunochemistry and subsequent c-fos quantitation.

DOI-induced head twitch

Mice were injected i.p. with 5 mg/kg of DOI. The number of head twitches was counted and recorded in 5 minute bins for the half hour period immediately after injection. A subset of the 5 mg/kg injections (N=7) were counted by 2 observers, one of whom was blinded to the genotype. A comparison of the results produced by the two different observers was not significantly different (data not shown). All the other head twitch experiments were performed by one blinded observer.

8-OH-DPAT-induced hypothermia

Rectal temperature was measured using the TH-5 Thermalert Monitoring Thermometer (Physitemp Instruments, Inc., Clifton, NJ) equipped with a RET-3 probe. The probe was sterilized with 70% ethanol and covered with vaseline before measuring each mouse's temperature. Mice were then injected i.p. with 5 mg/kg 8-OH-DPAT and rectal temperature was measured again 20 minutes later.

Western blot

DOI or vehicle was injected i.p., with light restraint to minimize stress effects, and then mice were sacrificed 15 minutes later by cervical dislocation. Microdissection was performed on ice as quickly as possible. Tissue was homogenized in 400 μL of SBB plus protease and phosphatase inhibitors and 5% glycerol. Tissue was spun for 10 min at 20–25,000 × g. The supernatant, which contains the proteins of interest, was collected and a protein assay performed for quantitation. SDS was added to 25 μg of protein boiled for 5 minutes to denature, and then used for Western blots. The following antibodies were used for Western, all at a 1:1000 dilution: rabbit polyclonal p-ERK1/2 (9101L, Cell Signaling), rabbit polyclonal ERK1/2 (9102L, Cell Signaling), p-GSK3β (9331, Cell Signaling), and rabbit monoclonal GSK3β (Cell Signaling, 9315).

PPI

All PPI experiments were performed at the Mouse Behavioral Phenotyping Laboratory Core Facility in the Neurodevelopmental Disorders Research Center at UNC Chapel Hill using the SR-Lab (San Diego Instruments). Briefly, mice were placed in a small, plexiglass cylinder housed within a large sound-proofed chamber. The cylinder is seated on a piezoelectric

transducer which quantifies movement-induced vibrations. The SR-Lab chamber also contains a light, fan, and loudspeaker for acoustic stimuli. Calibration of 70 dB background sound levels and prepulse acoustic stimuli was performed with a digital sound level meter (San Diego Instruments). Each session consisted of a 5 minute habituation period followed by 42 trials of 7 types – No Stimulation, 120 dB acoustic stimulus (AS50), and 5 different prepulse stimuli ranging from 4 dB over back ground (PP74) to 20 dB over background (PP90). The trial types were performed in 6 sets of 7, with the trial type order in each set randomized. Intertrial intervals were 10–20 seconds, with an average interval of 15 seconds. The AS50 was 40 ms long, while the prepulse stimulus was 20 ms long and occurred 100 ms before the onset of the startle stimulus. The sample window for measuring startle amplitude was 65 ms. The formula used to calculate % PPI was: ((AS50 − Startle After Prepulse)/AS50) × 100. Mice were injected with vehicle, PCP, or antipsychotic and PCP before being placed in the PPI chamber. When treated with vehicle or PCP, mice were immediately placed in the chamber. When treating with antipsychotic, mice were injected with antipsychotic 15 minutes before injecting PCP, after which mice were immediately placed in the chamber. There was a 1 week washout period between treatments.

PCP-induced hyperlocomotion

Locomotion was measured in a one hour session in an open field chamber (40 cm × 40 cm × 30 cm) crossed by a grid of photobeams (VersaMax system, AccuScan Instruments). The mice were injected with vehicle or SR46349B and placed in the chamber for a 20 minute acclimation period, and then they were injected with vehicle or PCP and locomotion was measured for one hour. Mice were treated with vehicle, 6.0 mg/kg PCP, or 1.0 mg/kg SR46349B + 6.0 mg/kg PCP. Mice were allowed a one week washout period between treatments. The number of photobeam breaks was counted during the 60 minute trial in five minute bins, and a total distance traveled in centimeters was calculated from the beam break counts.

Results

PSD-95 is essential for maintaining normal 5-HT$_{2A}$ and 5-HT$_{2C}$ receptor expression *in vivo*

Previous studies demonstrated that PSD-95 interacts with 5-HT$_{2A}$ (Xia et al., 2003a), (Xia et al., 2003b), (Becamel et al., 2004) and 5-HT$_{2C}$ (Becamel et al., 2002) receptors *in vitro* and *in vivo*. Additionally, ectopic expression of PSD- 95 inhibits the agonist-mediated internalization of the 5-HT$_{2A}$ receptor (Xia et al., 2003a), and promotes desensitization of 5-HT$_{2C}$ receptors (Gavarini et al., 2006) *in vitro*. Eliminating the Type I PDZ ligand motif abrogates both PSD-95 binding and functional activity *in vitro* (Xia et al., 2003a), (Xia et al., 2003b). What, if any, effect PSD-95 might have *in vivo* is unknown, although we predicted that PSD-95 is responsible for proper targeting and synaptic membrane stabilization of 5-HT$_{2A}$ and 5-HT$_{2C}$ serotonin receptors.

To test this prediction, we examined 5-HT$_{2A}$ and 5-HT$_{2C}$ receptor expression in PSD-95^{wildtype} and PSD-95^{null} mice. As seen in Figure 1A, PSD-95^{null} mice exhibit very little apical dendritic immunofluorescence as compared to PSD-95^{wildtype} litter-mate controls. We also performed saturation binding experiments with [^{3}H]-ketanserin on microdissected cortices to obtain a quantitative estimate of 5-HT$_{2A}$ receptor levels in null mice (Figure 1C). We determined that, consistent with our immunohistochemical findings, PSD-95^{null} mice exhibit a significant reduction in 5-HT$_{2A}$ receptor expression.

As shown in Fig 1B, PSD-95^{null} animals displayed even larger decrements of striatal and hippocampal 5-HT$_{2C}$ receptors as assessed by a 5-HT$_{2C}$-selective antibody. Saturation binding isotherms using [^{3}H]-mesulergine under conditions which selectively label 5-HT$_{2C}$ receptors

(see Methods) demonstrated a 72% reduction in 5-HT$_{2C}$ receptor expression levels in the hippocampus (Figure 1D).

PSD-95 regulates serotonin receptor turnover

We next examined several potential mechanisms which might account for the PSD-95-mediated modulation of 5-HT$_{2A}$ and 5-HT$_{2C}$ receptor expression. These included: (1) non-specific effects on the serotonin system; (2) PSD-95-mediated regulation of 5-HT receptor transcription and/or a generalized disruption of the machinery essential for neuronal regulation of receptors; (3) PSD-95-mediated alterations in serotonin receptor mRNA editing and (4) alterations in serotonin receptor turnover. Each of these possibilities will be dealt with in turn.

We first examined the possibility that genetic deletion of PSD-95 leads to generalized serotonergic system dysfunction leading to a reduction in serotonin receptor levels. We examined this first possibility by measuring the expression of a related 5-HT receptor which is also highly expressed in cortex and hippocampus but lacks a PDZ-ligand motif - the 5-HT$_{1A}$ receptor. As our saturation binding experiments using [^{3}H]-WAY100635 indicate, 5-HT$_{1A}$ expression levels were unchanged in PSD-95^{null} mice in both cortex (Figure 1C) and hippocampus (Figure 1D). These results indicate that genetic deletion of PSD-95 does not lead to a generalized alteration in the serotonergic system.

To examine the unlikely possibility that deleting PSD-95 leads to an alteration in 5-HT receptor gene transcription, we performed quantitative RT-PCR in order to measure 5-HT$_{2A}$ and 5-HT$_{2C}$ receptor mRNA levels. We found that 5- HT$_{2A}$ mRNA levels are unchanged in cortex (Figure 2A), and 5-HT$_{2C}$ mRNA levels are unchanged in hippocampus (Figure 2A). To further assess the role of PSD-95 in modulating mRNA levels more broadly, or the possibility that compensatory changes in global gene expression occur in null animals and that these compensatory changes cause the observed phenotypes, we performed whole-genome microarray analysis on cDNA prepared from PSD-95^{wildtype} and PSD-95^{null} cortices. Overall, there were few differences in transcript levels, and only 28 genes (27 genes decreased, 1 gene increased) appear to be modulated greater than 2-fold in the absence of PSD-95 - none of which are G-protein coupled receptors (GPCRs) or are expected to modulate the expression of 5-HT receptors (Supplementary Table 1). Thus, the whole genome microarray data are more consistent with a role for PSD-95 in post-transcriptional/post- translational regulation of 5-HT$_{2A}$ and 5-HT$_{2C}$ receptors.

Interestingly, 6 of the 28 genes, out of approximately 45,000 transcripts on the microarray, have previously been reported to be induced after hallucinogen administration (Table 1) (Gonzalez-Maeso et al., 2003), (Nichols and Sanders-Bush, 2002). In one study of transcripts induced by 5-HT$_{2A}$ agonists, only 3 of 13 transcripts shown to be changed by agonist administration were specific to hallucinogenic agonists (Gonzalez-Maeso et al., 2003). 2 of these 3 genes, *egr2* and *per1*, are down-regulated in the absence of PSD-95 according to our microarray data, which is consistent with a possible role of PSD-95 in mediating some 5-HT$_{2A}$ signaling pathways, particularly those related to hallucinogen actions.

The 5-HT$_{2C}$ receptor undergoes mRNA editing which modulates its constitutive activity, G-protein coupling efficiency, and expression (Niswender et al., 1999), (Price and Sanders-Bush, 2000). It is therefore conceivable that changes in 5-HT$_{2C}$ receptor expression are secondary to altered editing of 5-HT$_{2C}$ mRNAs. To examine this possibility, we examined RNA editing at all possible sites in PSD-95^{wildtype} and PSD-95^{null} hippocampal tissue, and we found that there is no change in the frequency of editing at any of the 5 sites (Figure 2B). Furthermore, there is no significant change in the proportions of 14 of the 15 different isoforms detected in the PSD-95^{null} mice as compared to PSD-95^{wildtype} mice (Figures 2C and 2D). An increase in PSD-95^{null} mice of 1 isoform out 15, the VSI isoform, is inconsistent with a role for mRNA

editing in down-regulating 5-HT$_{2C}$ receptors in PSD-95^{null} mice. These findings indicate that neither transcriptional nor post-transcriptional mechanisms (i.e., RNA editing) can account for the large effect that genetic deletion of PSD-95 has on the expression of 5-HT$_{2A}$ and 5-HT$_{2C}$ receptors.

Our data clearly point to the fourth prediction that PSD-95 is exerting its effect on the 5-HT$_{2A}$ and 5-HT$_{2C}$ receptors by regulating their turnover. Implicit in our hypothesis is that in the absence of PSD-95, 5-HT$_{2A}$ and 5-HT$_{2C}$ receptors will have greater access to intracellular trafficking machinery, or will enter alternative trafficking pathways, leading to higher rates of receptor turnover. To assess the rates of receptor turnover in PSD-95^{wildtype} and PSD-95^{null} animals, we took advantage of the properties of N-ethoxycarbonyl-1,2-ethoxydihydroquinolone (EEDQ), which binds irreversibly to 5-HT$_{2A}$ receptors (surface and intracellular), occluding them from recognition by their ligands after EEDQ treatment. By treating mice with EEDQ and modeling the rate of receptor recovery over time, one can measure the rate of 5-HT$_{2A}$ receptor turnover *in vivo* (Pinto and Battaglia, 1994).

For these studies we injected mice once with EEDQ (10 mg/kg), a dose that achieves approximately 90% irreversible blockade of 5-HT$_{2A}$ receptors, and performed saturation binding experiments at different time points after EEDQ treatment to measure the recovery rate of 5-HT$_{2A}$ receptors. If 5-HT$_{2A}$ receptors in null mice have a higher rate of turnover, then the rate constant of recovery (Pinto and Battaglia, 1994) should be higher in these mice. Consistent with this prediction, the modeled receptor recovery in PSD-95^{wildtype} and PSD-95^{null} mice (Figures 3A and 3B) showed that the rate constant, k (d^{-1}), was substantially higher in null mice. These findings indicate that genetic deletion of PSD-95 accelerates 5-HT$_{2A}$ receptor turnover *in vivo*. Attempts to perform similar studies with 5-HT$_{2C}$ receptors were unsuccessful due to the exceedingly low levels of 5-HT$_{2C}$ receptors expressed in PSD-95^{null} mice.

PSD-95 is required for the polarized sorting of 5-HT$_{2A}$ receptors to pyramidal neuron apical dendrites

Another important aspect of our hypothesis focuses on 5-HT$_{2A}$ receptors and the prediction that PSD-95 is crucial for proper targeting to the apical dendrites. Previous studies showed that mutating the PDZ ligand motif prevents dendritic targeting of the 5-HT$_{2A}$ receptor *in vitro* (Xia et al., 2003b). In order to determine if PSD-95 is one of the PDZ-domain proteins responsible for the preferential dendritic targeting of 5-HT$_{2A}$ receptors, we examined the ability of 5-HT$_{2A}$ receptors to be sorted to neuronal dendrites in cortical neurons prepared from PSD-95^{wildtype} and PSD-95^{null} mice.

For these studies, we performed confocal immunofluorescent studies of mouse cortical neurons for 5-HT$_{2A}$ receptors and the dendritic marker microtubule-associated protein 2 (MAP2) (Caceres et al., 1984). As Figures 4A and 4B illustrate, neurons prepared from PSD-95^{null} animals exhibit significantly lower 5-HT$_{2A}$ receptor expression in both the neuronal soma and dendrites - a finding consistent with our *in vivo* data. In order to examine the impact of PSD-95 on dendritic trafficking, we also calculated a 5-HT$_{2A}$ receptor cell body/dendrite expression (CB/D) ratio. If dendritic targeting is impaired in PSD-95^{null} neurons, we predicted that the CB/D ratio should be higher in these neurons, as impairment of 5-HT$_{2A}$ trafficking to dendrites should result in a relative accumulation of receptors in the neuronal cell body. As predicted, Figure 4B confirms that the CB/D ratio is higher in PSD-95^{null} neurons.

If PSD-95 is essential for 5-HT$_{2A}$ expression and sorting to the dendrites, re-introduction of PSD-95 should increase receptor expression in both the neuronal soma and dendrites. Furthermore, PSD-95 re-expression should decrease the CB/D ratio, representing an increase in dendritic targeting of receptor. To assess the effect of re-expression of PSD-95 on 5-HT$_{2A}$

expression and targeting, we generated PSD-95-GFP lentivirus and a control GFP lentivirus and infected cortical neuronal cultures prepared from PSD-95[null] animals (Figure 5A). PSD-95-GFP expression led to an approximately 2-fold increase in cell body 5-HT$_{2A}$ expression and an approximately 5-fold increase in dendritic 5-HT$_{2A}$ expression as compared to GFP expression in neurons prepared from the same PSD-95[null] animals (Figure 5B). Furthermore, as predicted, the CB/D ratio is greatly decreased in PSD-95[null] neurons expressing PSD-95-GFP as compared to those expressing the control GFP (Figure 5B).

PSD-95 is required for 5-HT$_{2C}$ signaling *in vivo*

Having provided strong evidence that PSD-95 profoundly regulates the expression of 5-HT$_{2C}$ receptors, we next examined the consequences of knocking out PSD-95 on 5-HT$_{2C}$ function *in vivo*. It is well established that *c-fos* is an immediate early gene (IEG) which is transcribed after GPCR activation (Lo and Wong, 2006) and which is useful as a general marker of neuronal activity (Chaudhuri, 1997). To examine the consequences of genetic deletion of PSD-95 on signaling downstream of the 5-HT$_{2C}$ receptor and on neural activity, we treated mice with MK-212, a 5-HT$_{2C}$-selective agonist (Thomsen et al., 2008), and assessed induction of c-fos in the hippocampus. Significantly, we found that the number of c-fos-positive cells after MK-212 treatment was greatly reduced in PSD-95[null] animals in a number of hippocampal subregions (Figures 6A–B and Supplemental Figure S1). Our finding that MK-212 induces the largest c-fos response in the dentate gyrus region of the hippocampus is in accordance with prior studies (Campbell and Merchant, 2003). This reduction did not appear to be related to alterations in hippocampal morphology or volume, as cresyl violet staining does not reveal any gross abnormalities in the absence of PSD-95 (Supplemental Figure S2). Furthermore, the thickness of the stained regions (in CA1-CA3, the pyramidal layer; in DG, the granular layer) was unchanged in PSD-95[null] mice (Supplemental Figure S2). This decrease in c-fos induction seen in all hippocampal regions measured was highly significant (Figure 6C) and indicates that genetic deletion of PSD-95 greatly attenuates 5-HT$_{2C}$ signaling *in vivo*.

PSD-95 is essential for hallucinogen actions *in vivo*

We also predicted that the alterations in 5-HT$_{2A}$ expression induced by deleting PSD-95 should lead to a reduction in hallucinogen actions *in vivo*. Although a number of animal models have been proposed for studying hallucinogen action in rodents (Nichols, 2004), head twitch behavior has been shown to be the most specific for hallucinogenic action in that non-hallucinogenic 5-HT$_{2A}$ agonists such as lisuride do not induce the behavior (Gonzalez-Maeso et al., 2007). PSD-95[wildtype] and PSD-95[null] mice were injected with a 5 mg/kg dose of the prototypical 5-HT$_{2A}$ hallucinogen 1-(4-iodo-2,5-dimethoxyphenyl)propan-2- amine hydrochloride (Imamura et al., 2002). We found that there was a large and significant decrease in DOI-induced head twitch in PSD-95[null] animals as compared to PSD-95[wildtype] animals (Figure 7A). Head twitches are virtually nonexistent in both PSD-95[wildtype] and PSD-95[null] animals after saline treatment (0–2 per 30 minutes, data not shown). In contrast, 8-Hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT), which is known to induce hypothermia via agonist action at 5-HT$_{1A}$ receptors in the CNS (Martin et al., 1992), leads to the same decrease in temperature in both PSD-95[wildtype] and PSD-95[null] mice (Figure 7A). Together, the findings suggest that PSD-95 selectively affects behaviors mediated by 5-HT$_{2A}$ receptors.

Given the reduction in DOI-induced head twitch seen in the absence of PSD-95 *in vivo*, we also predicted that 5-HT$_{2A}$-mediated signaling would be reduced or absent in PSD-95[null] mice. The 5-HT$_{2A}$ receptor has been shown to signal through a large number of canonical (PLCβ) and non-canonical (PLA$_2$, PLD, etc.) pathways (Nichols, 2004). The evidence thus far suggests that hallucinogen action is not correlated with canonical signaling pathways, since both hallucinogenic and non-hallucinogenic agonists at the 5-HT$_{2A}$ receptor activate those pathways with similar potencies (Nichols, 2004). 5-HT$_{2A}$ agonists have been shown to activate ERK1/2

via a number of different mechanisms (Hershenson et al., 1995), (Quinn et al., 2002), (Gooz et al., 2006), (Greene et al., 2000), and 5-HT$_{2A}$ agonists also lead to Akt activation (i.e., Akt phosphorylation) (Johnson-Farley et al., 2005). Phosphorylation of Akt leads to phosphorylation of GSK3β, which renders that protein inactive (Beaulieu et al., 2008). Accordingly, we predicted that the induction of phospho-ERK1/2 (pERK1/2) and phospho-GSK3β (p-GSK3β) after treatment with DOI (5 mg/kg) would be reduced or absent in PSD-95[null] mice (Schmid et al., 2008), (Li et al., 2004). Consistent with our prediction, we found that DOI was unable to induce pERK1/2 or pGSK3β in PSD-95[null] mice (Figures 7B–D). Thus, our evidence suggests that PSD-95 plays an important role in mediating 5-HT$_{2A}$ downstream signaling, and its absence results in signaling and behavioral abnormalities.

Deletion of PSD-95 renders atypical antipsychotics ineffective

It has been recently demonstrated that synaptic and behavioral measures of dopamine-mediated synaptic plasticity are also altered by genetic deletion of PSD-95 (Yao et al., 2004). We thus hypothesized that the prototypical, gold standard atypical antipsychotic drug clozapine, whose actions are mediated via inverse agonism at 5-HT$_{2A}$ and 5-HT$_{2C}$ receptors (Meltzer et al., 1989), (Rauser et al., 2001) and by weak D2/D3/D4-dopamine antagonism (Roth et al., 2004b), would have an altered activity in PSD-95[null] mice. In this regard, the phencyclidine (PCP)-induced disruption of prepulse inhibition (PPI) is a well-accepted pharmacological model of schizophrenia (Geyer et al., 2001), (Linn and Javitt, 2001). Importantly, clozapine preferentially normalizes PCP-induced disruption of PPI in both rodents and monkeys, while typical antipsychotics like haloperidol have little to no effect (Geyer et al., 2001), (Linn et al., 2003). As all the published evidence suggests that 5-HT$_{2A}$ receptors are important in mediating clozapine's reversal of the PCP-induced disruption of PPI (Yamada et al., 1999), we predicted that clozapine would exhibit an altered ability to inhibit PCP-induced disruption of PPI in PSD-95[null] mice.

In order to test this prediction, we injected littermate pairs of PSD-95[wildtype] and PSD-95[null] mice with vehicle, PCP, or clozapine plus PCP, followed by PPI assessment. PCP significantly disrupted PPI at all prepulse levels in PSD-95[wildtype] mice, and at two of the four prepulse levels in PSD-95[null] mice (Figure 8A and Supplemental Figure S3). Clozapine normalized the PCP-induced deficit of PPI in PSD-95[wildtype] mice while having no significant effect in PSD-95[null] mice. As a control, we also measured startle response and found no significant effect of genotype on startle response (AS50) with and without drug treatments (Supplemental Figure S3), and clozapine treatment alone had no effect on PPI in comparison to vehicle-treated mice (Figure 8B). Thus, genetic deletion of PSD-95 abolishes the antipsychotic-like actions of clozapine.

Though the actions of clozapine in NMDA-antagonist-based psychosis models such as PCP-induced disruption of PPI are known to be 5-HT$_{2A}$-mediated, clozapine is nonetheless a pharmacologically "dirty" drug, with a high affinity for a number of other receptors (Roth et al., 2004a). In order to more firmly establish that 5-HT$_{2A}$ dysfunction is responsible for the abnormal antipsychotic-like efficacy seen in the aforementioned clozapine experiment, we utilized two selective antagonists of the 5-HT$_{2A}$ receptor, M100907 and SR46349B, which have been shown to be effective in NMDA antagonist-based animal models of psychosis (Varty et al., 1999) and in clinical studies of schizophrenic patients (Meltzer et al., 2004). If the impaired efficacy of clozapine is due to 5-HT$_{2A}$ dysfunction, then 5-HT$_{2A}$ antagonists should be ineffective as antipsychotics in multiple psychosis models. In this experiment, PCP significantly disrupted PPI at 4 and 8 dB in both PSD-95[wildtype] and PSD-95[null] mice (Figure 8C). As predicted, pre-treatment with M100907 (0.5 mg/kg) or SR46349B (1 mg/kg) normalized PCP-induced disruption of PPI in PSD-95[wildtype] mice only, having no effect in PSD-95[null] mice (Figure 8C). In order to provide further evidence that antipsychotic-like

efficacy mediated by 5-HT$_{2A}$ receptors is impaired in the absence of PSD-95, we examined the effect of SR46349B (1 mg/kg) in another widely used animal model of psychosis, PCP-induced hyperlocomotion, which is also normalized by atypical antipsychotics such as clozapine (Gleason and Shannon, 1997), (Geyer and Ellenbroek, 2003). As expected, SR46349B (1 mg/kg) normalizes PCP-induced hyperlocomotion in PSD-95^{wildtype}, but not PSD-95^{null} mice (Figure 8D). Thus, our findings are very consistent in showing that the genetic deletion of PSD-95 leads to 5-HT$_{2A}$ receptor dysfunction which in turn prevents atypical antipsychotics from being therapeutically efficacious in animal models of psychosis.

Discussion

The main finding of this paper is that PSD-95 is essential for serotonin receptor function and hallucinogen and atypical antipsychotic actions *in vivo*. These findings suggest that in addition to its well-known modulatory effect on ionotropic glutamatergic signaling, PSD-95 is required for normal metabotropic serotonin receptor function. We show that PSD-95, a modular PDZ domain-containing protein which scaffolds a wide range of proteins at postsynaptic clusters, is an important regulatory partner for both 5-HT$_{2A}$ and 5-HT$_{2C}$ receptors *in vivo*. In the absence of PSD-95, the 5-HT$_{2A}$ receptor has accelerated receptor turnover kinetics and decreased targeting to the appropriate dendritic compartment, leading to a decrease in total receptor expression and a concomitant decrease in 5-HT$_{2A}$-mediated signaling (p-ERK1/2 and p-GSK3β) and behaviors (e.g. head-twitch response). In the absence of PSD-95 the 5-HT$_{2C}$ receptor exhibits a larger decrease in receptor protein expression and downstream signaling. Finally, we show that, in the absence of PSD-95, the prototypical atypical antipsychotic drug clozapine, as well as the selective 5-HT$_{2A}$ antagonists M100907 and SR46349B, are unable to mediate their therapeutic effects in animal psychosis models.

5-HT$_{2C}$ receptors, PSD-95, and psychiatric disease

There is considerable evidence that 5-HT$_{2C}$ serotonin receptors regulate hippocampal function. Genetic evidence from 5-HT$_{2C}$ knockout mice shows that long term potentiation (LTP) is impaired in the dentate gyrus in the absence of 5-HT$_{2C}$ receptors (Tecott et al., 1998). 5-HT$_{2C}$ knockout mice also exhibit defects in behaviors thought to be mediated by the dentate gyrus (Tecott et al., 1998), and are more susceptible to spontaneous and audiogenic seizures (Tecott et al., 1995), which are known to involve limbic recruitment (Wieraszko and Seyfried, 1993), (Pereira et al., 2008).

Despite this evidence that 5-HT$_{2C}$ receptors modulate neuronal function, nothing is known regarding their targeting and regulation of neuronal expression. Our data concerning the 5-HT$_{2C}$ receptor's interaction with, and regulation by, PSD-95, suggests that the 5-HT$_{2C}$ receptor is present at PSD-95-enriched neuronal domains where it would be well placed to influence neuronal excitability and synaptic properties, and therefore brain electrical activity. Though our studies focused on 5-HT$_{2C}$ function in the hippocampus, the potential relevance of our findings to 5-HT$_{2C}$ function in other brain regions is also of interest. The 5-HT$_{2C}$ receptor has shown promise as a target in the treatment of a number of psychiatric disorders, including in particular schizophrenia and obesity, though it has been proposed that 5-HT$_{2C}$ receptors may also play a role in the etiology and treatment of OCD and depression (Gray and Roth, 2007), (Dunlop et al., 2005), (Marquis et al., 2007), (Dunlop et al., 2006), (Sard et al., 2005). Thus, PSD-95 may play a role in regulating 5-HT$_{2C}$ function in various disease states, although further study will be needed to investigate this intriguing possibility.

Implications of PSD-95 regulation of hallucinogen action

Though it is known that hallucinogens exert their effects via activation of the 5-HT$_{2A}$ receptor (Glennon et al., 1983), the signaling processes underlying hallucinogen action are still poorly

characterized. Recent evidence suggests that cortical 5-HT$_{2A}$ receptors are required for hallucinogen actions, possibly by facilitating cortico-cortical activity (Gonzalez-Maeso et al., 2007). Our data is relevant in several respects. First, our findings are consistent with the hypothesis that hallucinogens exert their effects at cortical pyramidal neuron apical dendrites. Apical dendritic activity has been implicated as forming the neural basis for cognition and consciousness (LaBerge, 2006), (Laberge and Kasevich, 2007), and it is thought that cortico-cortical connections, which are primarily composed of synaptic contacts at apical dendrites (Spratling, 2002), are important in generating and shaping the neural activity that underlies consciousness (Tononi and Edelman, 1998). Furthermore, the primary neuro-anatomical site of expression of 5-HT$_{2A}$ receptors is the apical dendrites of cortical pyramidal neurons, particularly in layer V pyramidal neurons (Willins et al., 1997), (Jakab and Goldman-Rakic, 1998). Finally, a wide range of evidence supports altered glutamatergic signaling in neocortex as playing a key role in mediating the effects of hallucinogens on consciousness (Aghajanian and Marek, 1999). Importantly, our studies demonstrate that the overall expression and apical dendritic targeting of 5-HT$_{2A}$ receptors to postsynaptic densities is significantly impaired in cortical neurons prepared from PSD-95^{null} mice. Also, DOI is unable to induce p-ERK1/2 and p-GSK3β in PSD-95^{null} mice. Not surprisingly, DOI-induced head twitch behavior, the behavioral correlate of hallucinogen action, is also reduced. Moreover, we found that the re-introduction of PSD-95 into PSD-95^{null} neurons rescues both the deficient expression and targeting phenotype.

Our data provide a mechanism whereby 5-HT$_{2A}$ receptors can be targeted to a cortical, postsynaptic site of action and trafficked appropriately once they have arrived. In fact, our studies have provided the first candidate subcellular locus for hallucinogen action, the PSD-95-scaffolded macromolecular signaling complex of cortical neurons. Given the accumulating evidence that hallucinogenic action involves alterations in synaptic activity, our data further suggest the possibility that hallucinogens may exert their actions via PSD-95-mediated interactions with glutamatergic signaling complexes downstream of 5- HT$_{2A}$ receptor activation.

Atypical antipsychotics are ineffective in the absence of PSD-95

It has been known for some time that PCP, a non-competitive NMDA receptor antagonist, induces psychotic and 'deficit' states that are nearly indistinguishable from the positive and negative symptoms of schizophrenia (Jentsch and Roth, 1999), (Olney et al., 1999), (Javitt, 2004). Furthermore, clozapine and other drugs with potent 5-HT$_{2A}$ inverse agonist actions ameliorate PCP-induced PPI deficits (Geyer et al., 2001), (Linn et al., 2003), (Carlsson et al., 1999), (Yamada et al., 1999). Finally, genetic deletion of PSD-95 or deletion of one of the PDZ domains results in abnormalities in LTP, a phenotype related to glutamatergic dysfunction (Migaud et al., 1998), (Yao et al., 2004). Together with our data, the evidence suggest that one of the key subcellular locations at which the functional interplay between 5-HT$_{2A}$ receptors and glutamatergic signaling takes place is the PSD-95-scaffolded postsynaptic density.

Since, in the absence of PSD-95, glutamatergic signaling is abnormal, and 5-HT$_{2A}$ receptors are mis-targeted and mis-trafficked, we predicted that there may be abnormalities in the ability of clozapine and selective 5-HT$_{2A}$ antagonists to alleviate PCP-induce psychotic-like behaviors in mice. We found that clozapine, M100907, or SR46349B treatment, which reduced PCP-induced deficits of PPI in PSD-95^{wildtype} mice, was completely ineffective in PSD-95^{null} mice. The dramatically impaired antipsychotic-like action of the aforementioned atypical antipsychotics in the PSD-95^{null} mice is likely due to the combined abnormalities in 5-HT$_{2A}$ and 5-HT$_{2C}$ receptor function – both of which have long been thought to be essential for their unique benefits (Roth et al., 2004a). Our studies clearly implicate the 5-HT$_{2A}$

dysfunction that results in the absence of PSD-95 as being responsible for the lack of atypical antipsychotic efficacy in PSD-95[null] mice.

Conclusions

In this paper we demonstrate that PSD-95, in addition to its well known role in scaffolding glutamatergic signaling complexes and facilitating neuronal plasticity, potently regulates neuronal metabotropic serotonin receptor targeting, trafficking, and signaling *in vivo*. Furthermore, we show that the absence of PSD-95 results in abnormal downstream signaling for both 5-HT$_{2A}$ receptors and 5-HT$_{2C}$ receptors, both of which are important therapeutic targets for a number of psychiatric diseases. We also show that the 5-HT$_{2A}$ dysfunction has profound consequences with regards to the treatment of psychotic-like states in relevant animal models. Our findings demonstrate an unexpectedly profound role for PSD-95 in regulating 5-HT$_{2A}$ and 5-HT$_{2C}$ receptor function and the behavioral responses to drugs acting at these receptors. These results imply that PSD-95 may serve as a scaffold to integrate information between ionotropic and metabotropic neurotransmission at postsynaptic densities.

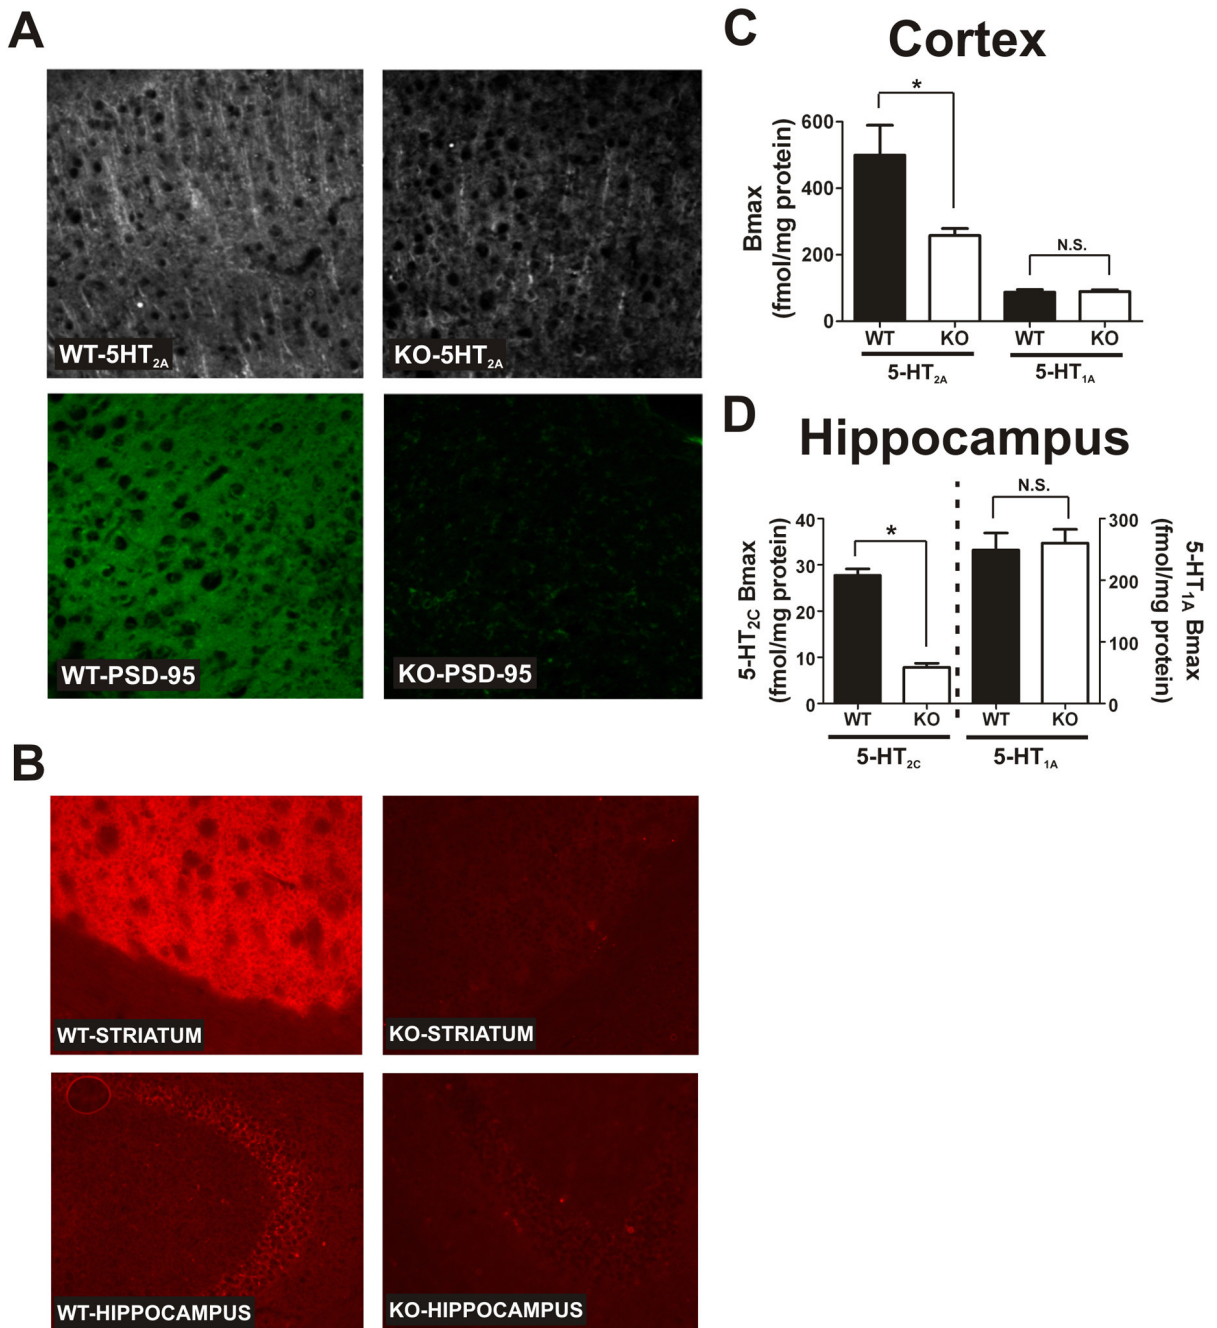

Figure 1. Genetic deletion of PSD-95 results in a selective loss of 5-HT$_{2A}$ and 5-HT$_{2C}$ receptors
(A) 5-HT$_{2A}$ and PSD-95 double-label immunochemistry in medial prefrontal cortex of PSD-95^{wildtype} and PSD-95^{null} mice shows a large reduction in 5-HT$_{2A}$ receptor expression in null mice (N=3 littermate pairs). (B) 5-HT$_{2C}$ immunochemistry in PSD-95^{wildtype} and PSD-95^{null} striatum and hippocampus reveals that 5-HT$_{2C}$ receptor expression is almost completely abolished in the absence of PSD-95 in both striatum and hippocampus (N=3 littermate pairs). (C) Comparison of B$_{max}$ estimates for the 5-HT$_{2A}$ receptor (N=4 littermate pairs) and the 5-HT$_{1A}$ receptor (N=5 littermate pairs) in PSD-95^{wildtype} and PSD-95^{null} cortices. B$_{max}$ estimates were obtained by performing [^{3}H]-ketanserin (5-HT$_{2A}$) and [^{3}H]-WAY100635 (5- HT$_{1A}$) saturation binding on microdissected and homogenized cortical tissue.

Quantitation showed a roughly 40% reduction in $5\text{-}HT_{2A}$ expression and no change in $5\text{-}HT_{1A}$ expression in the cortices of PSD-95^{null} mice. (D) Comparison of B_{max} estimates for the $5\text{-}HT_{2C}$ receptor (N=3; tissue from 3 animals was pooled for each measurement, for a total of 9 animals, all littermate pairs) and $5\text{-}HT_{1A}$ receptor (N=6 littermate pairs) in PSD-95^{wildtype} and PSD-95^{null} hippocampi. B_{max} estimates were obtained by performing [^{3}H]-mesulergine saturation binding in the presence of 100 nM spiperone to block the vast majority of $5\text{-}HT_{2A}$ receptors (5- HT_{2C}) and [^{3}H]-WAY100635 saturation binding ($5\text{-}HT_{1A}$). Quantitation showed an almost 70% reduction in $5\text{-}HT_{2C}$ expression and no change in $5\text{-}HT_{1A}$ expression in hippocampus in the absence of PSD-95. All saturation binding was analyzed using non-linear least squares fitting. B_{max} data are presented as means +/- SEM. *p < .05, **p < .01, ***p < . 001; one-tailed unpaired t-test.
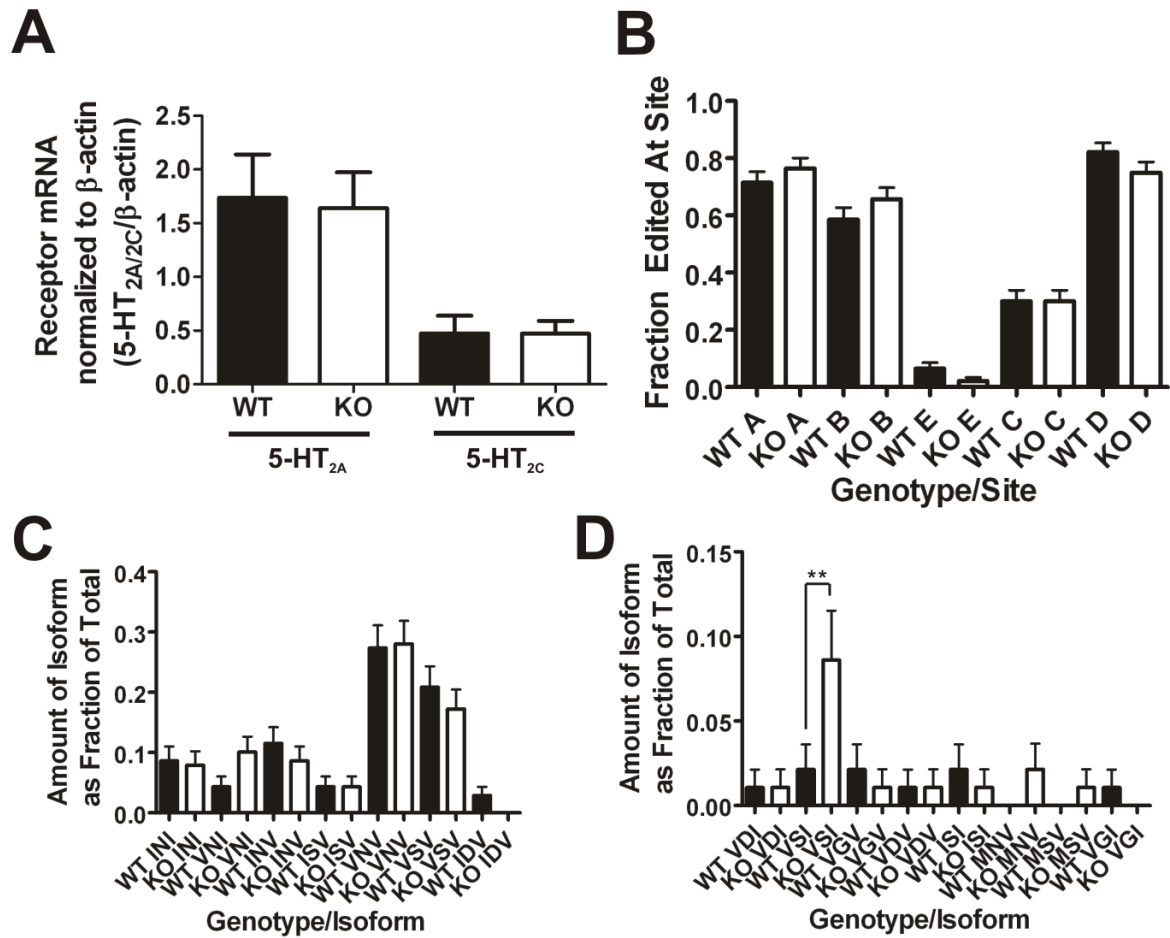

Figure 2. Genetic deletion of PSD-95 does not affect mRNA levels of 5- HT$_{2A}$ and 5-HT$_{2C}$ receptors or mRNA editing of the 5-HT$_{2C}$ receptor

(A) Cortical 5-HT$_{2A}$ receptor mRNA levels (N=4 littermate pairs; 11 measurements were performed for each animal) and hippocampal 5-HT$_{2C}$ receptor mRNA levels (N=4 littermate pairs; 5 measurements for each animal) normalized to β-actin mRNA levels as measured by quantitative RT-PCR. There are no changes in 5-HT$_{2A}$ mRNA levels and no changes in 5-HT$_{2C}$ mRNA levels in the absence of PSD-95. (B) 5-HT$_{2C}$ mRNA editing frequencies at 5 edited sites. The frequency of editing at the 5 sites is not significantly different in PSD-95[null] mice. (C) and (D) Frequencies of the different edited isoforms detected (wildtypes, N=94; nulls N=93). 15 isoforms were detected, and 14 of them were not significantly altered in the absence of PSD-95. There is a significant increase in the proportion of the VSI isoform in PSD-95[null] mouse hippocampus. All mRNA editing data are plotted as the frequency expressed as a fraction of the total, +/-the SEM. Normalized mRNA measurements are presented as means +/− SEM. $^*p < .05$, $^{**}p < .01$, $^{***}p < .001$; one-tailed unpaired t-test for the comparison of mRNA levels and one-way ANOVA followed by Newman-Keuls post-hoc tests for comparison of the mRNA editing measurements.
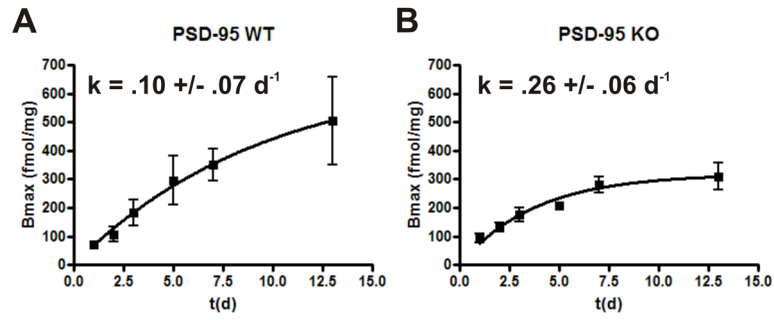

Figure 3. Genetic deletion of PSD-95 leads to an accelerated turnover of 5- HT_{2A} receptor protein
(A) and (B) represent fitted curves modeling 5-HT_{2A} receptor turnover in PSD- 95^{wildtype} and PSD-95^{null} mice, respectively, (N=3–4 littermate pairs at each data point). Visual inspection shows that steady state levels for the 5-HT_{2A} receptor are reached sooner in the absence of PSD-95, suggesting accelerated turnover. The higher k in PSD-95^{null} cortex indicates a higher rate of receptor turnover in the absence of PSD-95. Rate constant, k, is a non least squares fitted parameter of an equation modeling receptor recovery (see methods for details), +/− SEM. *p < .05, **p < .01, ***p < .001; one-tailed unpaired t-test.
Figure 4. 5-HT$_{2A}$ receptor expression and dendritic targeting is attenuated in neurons prepared from PSD-95^{null} mice

(A) Representative images of double-label immunochemistry performed on P0.5 cortical neurons of PSD-95^{wildtype} and PSD-95^{null} mice. The red arrows highlight the same dendritic process in all 3 images of each neuron. MAP2-positive dendrites display reduced 5-HT$_{2A}$ receptor expression in the absence of PSD-95. (B) Comparison of 5-HT$_{2A}$ receptor expression, normalized to MAP2 expression, in cell bodies and dendrites, and cell body to dendritic (CB/D) expression ratio, in PSD-95^{wildtype} and PSD-95^{null} neurons. Quantitation of 5-HT$_{2A}$ receptors shows that in PSD-95^{null} neurons, expression is dramatically reduced in both neuronal soma and dendrites. The increase in the CB/D ratio in PSD-95^{null} neurons suggests

an impairment in dendritic targeting in the absence of PSD-95. N=3 littermate pairs, 17 neurons from each animal, for a total of 51 neurons measured per genotype. Data are presented as the mean +/− the SEM. [*]p < .05, [**]p < .01, [***]p < .001; one-tailed unpaired t-test.
Figure 5. Re-introduction of PSD-95 rescues 5-HT$_{2A}$ receptor expression and trafficking deficits in PSD-95^{null} cortical neurons *in vitro*

(A) Representative images of double-label immunochemistry performed on P0.5 cortical neurons of PSD-95^{null} mice infected with either GFP lentivirus (top two rows of panels) or PSD-95-GFP lentivirus (bottom two rows of panels). PSD-95^{null} neurons from each animal were plated in two wells, one for GFP lentiviral infection and the other for PSD-95-GFP lentiviral infection. The yellow arrows highlight dendritic 5-HT$_{2A}$ receptor expression in an infected neuron. White arrows highlight 5-HT$_{2A}$ receptor expression in an uninfected neuron. GFP-infected neurons display low overall 5-HT$_{2A}$ expression and low dendritic targeting. In contrast, PSD-95-GFP-infected neurons display a dramatic increase in overall 5-HT$_{2A}$ receptor

expression and substantially more receptor appears to be targeted to the dendritic compartment, both in comparison to control GFP- infected neurons and in comparison to uninfected neurons in the same field. (B) Comparison of 5-HT$_{2A}$ receptor expression in cell bodies and dendrites and the CB/D ratio in GFP- and PSD-95-GFP- infected PSD-95^{null} neurons. Expression is normalized to GFP or PSD-95-GFP. PSD-95-GFP leads to substantial rescue of 5-HT$_{2A}$ receptor expression in comparison to GFP-infected control neurons. PSD-95-GFP addback leads to a significant reduction in the CB/D ratio in comparison to GFP-expressing control neurons, suggesting that PSD-95-GFP is rescuing dendritic targeting of 5-HT$_{2A}$ receptor expression. N=3 animals for each animal/lentivirus, and 10 infected neurons from each animal/ lentivirus were measured (60 neurons total). Data are presented as the mean +/- the SEM. *p < .05, **p < .01, ***p < .001; one-tailed unpaired t-test.
Figure 6. Deletion of PSD-95 attenuates 5-HT$_{2C}$ receptor-mediated induction of c-fos
(A) 5-HT$_{2C}$ and c-fos double-label immunochemistry in the hippocampus of PSD- 95^{wildtype} and PSD-95^{null} mice after MK-212 treatment (N=3 littermate pairs). Representative images of CA1 and CA2 are shown. There are fewer c-fos-positive cells in the PSD-95^{null} mice treated with MK-212 in both CA1 and CA2. (B) Higher magnification image of CA1 in order to examine co-localization of 5- HT$_{2C}$ receptors and c-fos. 5-HT$_{2C}$ receptor co-localizes with c-fos, suggesting that 5-HT$_{2C}$ is inducing this IEG directly, rather than indirectly in surrounding neurons. (C) Analysis of c-fos induction was performed by counting the number of c-fos-positive cells in CA1, CA2, CA3, and dentate gyrus (DG). Data are presented as the mean number of c-fos-positive cells +/− the SEM. There is a significant reduction in c-fos-positive

cells in the absence of PSD-95 in all four regions that were measured. c-fos counts were performed separately in the hippocampus of each hemisphere (2 values for each section analyzed). Every 7th section was analyzed, for a total of 6 sections per animal. [*]$p < .05$, [**]$p < .01$, [***]$p < .001$; one-tailed unpaired t-test.
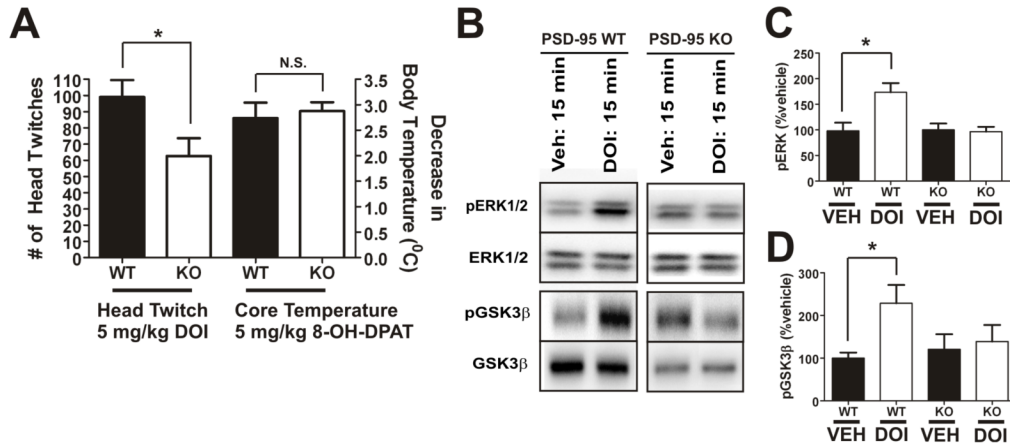

Figure 7. 5-HT$_{2A}$-mediated head twitch behavior is attenuated in PSD-95^{null} mice
(A) 5-HT$_{2A}$-mediated head twitch response after i.p. injection of 5 mg/kg DOI (N=11 littermate pairs) and 5-HT$_{1A}$-mediated hypothermic response after i.p. injection of 5 mg/kg 8-OH-DPAT (N=12 littermate pairs). There is a significant decrease in DOI-induced head twitch in PSD-95^{null} mice, in contrast with the magnitude of the decrease in core body temperature induced by 8-OH-DPAT, which is the same in both PSD-95^{wildtype} and PSD-95^{null} mice. (B), (C), and (D) Western blot and associated quantification for p-ERK1/2, ERK1/2, p-GSK3β, and GSK3β 15 minutes after i.p. injection of vehicle or DOI (N=4–5 littermate pairs). DOI induces pERK1/2 and pGSK3β in wildtype, but not null, mice. For quantification, p-ERK1/2 and p-GSK3β were normalized to ERK1/2 and GSK3β, respectively. Data are given as means +/− the SEM. $^{*}p < .05$, $^{**}p < .01$, $^{***}p < .001$; one-tailed unpaired t-test.
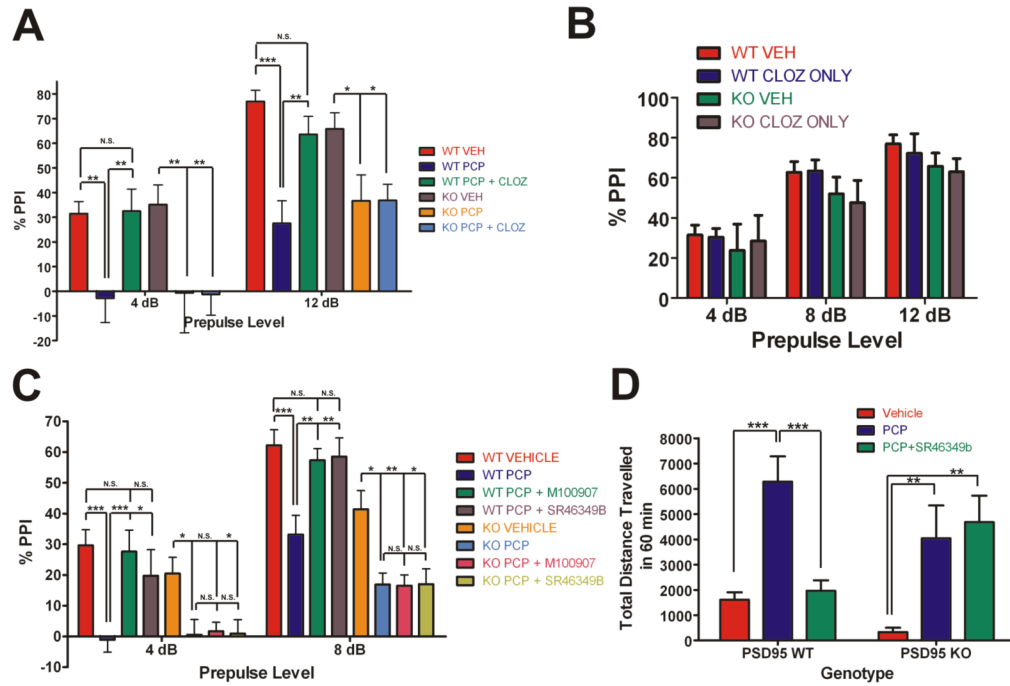

Figure 8. The antipsychotic-like efficacy of atypical antipsychotics is lost in PSD-95[null] mice

At the 2 prepulses shown, 4 and 12 dB, PCP significantly disrupted PPI in PSD-95[wildtype] and PSD-95[null] mice. In PSD-95[wildtype] mice, clozapine pre-treatment normalized the disruption of PPI by PCP at both 4 and 12 dB (N=6 littermate pairs). In contrast, in PSD-95[null] mice, clozapine had no antipsychotic-like effect. (B) PPI after treatment with clozapine alone (N=6 littermate pairs). 0.5 mg/kg clozapine had no effect on PPI in comparison to vehicle. (C) PPI in PSD-95[wildtype] and PSD-95[null] mice after injection of vehicle, 6.0 mg/kg PCP, 0.5 mg/kg M100907 + 6.0 mg/kg PCP, or 1.0 mg/kg SR46349B + 6.0 mg/kg PCP. PCP significantly disrupted PPI in PSD-95[wildtype] and PSD-95[null] mice at 4 and 8 dB (N=12). In PSD-95[wildtype] mice, M100907 or SR46349B pre-treatment normalized the disruption of PPI by PCP at 4 and 8 dB, whereas in PSD-95[null] mice, they had no antipsychotic-like effect. (D) Locomotion after vehicle, 6.0 mg/kg PCP, and 1.0 mg/kg SR46349B + 6.0 mg/kg PCP in PSD-95[wildtype] and PSD-95[null] mice (N=12). SR46349B normalizes PCP-induced hyperlocomotion in PSD-95[wildtype] mice only. Data are given as means +/- the SEM. $^*p < .05$, $^{**}p < .01$, $^{***}p < .001$; Two-way repeated measures ANOVA followed by Bonferroni post-tests.

Table 1
Genes of interest affected in PSD-95[null] mice

6 transcripts that are downregulated in PSD-95[null] mice have been reported to be induced after hallucinogenic drug administration in mice. Most are immediate early genes, which is consistent with a role for PSD-95 in regulating 5-HT$_{2A}$ signaling.

Gene of Interest	Alternate Names	Dowregulation as % of Wildtype
Arc[b]	rg3.1	36.6
egr2[a,b]	krox20; ngf1b; zfp-25; zfp-6	38.6
per1[a]	rigui	42.0
Jun-B[a]	-	46.7
Nr4a1[a]	N-10; gfrp; gfrp1; hbr-1; hmr; np10; tr3; nur77; tis1	50
Homer1a[b,*]	-	35.3

[a](Gonzalez-Maeso, Yuen et al. 2003)

[b](Nichols and Sanders-Bush 2002)

[*] the gene previously reported to be upregulated after hallucinogen administration is *ania3*, a closely related isoform that differs only in the 5′ UTR and a few amino acids at the C-terminus
